(54) Title: ADAPTIVE FOCUSING AND NULLING HYPERTHERMIA ANNULAR AND MONOPOLE PHASED ARRAY APPLICATORS

## (57) Abstract

An R.F. hyperthermia phased array applicator uses adaptive nulling and focusing with non-invasive electric field probes (112) to control the electric field intensity at selected positions in and around a target body (106) to provide improved heating of solid tumors (107) during hyperthermia treatment. A gradient search or matrix inversion algorithm is used to control the amplitude and phase weighting for the phased array transmit elements (104) of the hyperthermia applicator. A 915 MHz monopole phased array hyperthermia applicator for heating brain tumors has an enclosed vessel including a plurality of monopole transmit antenna elements disposed as a circular arc array on a ground plane which has an aperture for positioning the tumor in proximity to the monopole antenna elements. Adaptive focusing with non-invasive electric field probes is used to maximize the electric field at the tumor site. Parallel plate microwave waveguides are used to direct R.F. energy from the monopole phased array to the tumor site. A microwave transmit and receive module generates amplitude and phase controlled transmit signals for exciting the monopole antenna elements, and receives passive microwave signals from the monopole antenna elements for taking non-invasive radiometry temperature measurements of the tumor site.

10

BACKGROUND OF THE INVENTION

The successful treatment of deep-seated malignant tumors within a  
patient is often a difficult task. The objective of the treatment is to reduce  
in size or completely remove the tumor mass by one or more modalities  
available at the treatment facility. Common treatment modalities are  
15 surgery, chemotherapy, and x-ray therapy. One treatment modality used  
alone or in conjunction with one of the above modalities is "tissue  
heating", or hyperthermia. Hyperthermia can be considered as a form of  
high fever localized within the body. A controlled thermal dose  
distribution is required for hyperthermia to have a therapeutic value.  
20 Typical localized-hyperthermia temperatures required for therapeutic  
treatment of cancer are in the 43-45°C range. Normal tissue should be  
kept at temperatures below 43°C during the treatment. Typically,  
hyperthermia is induced in the body by radio-frequency (RF) waves,  
acoustic (ultrasound) waves, or a combination of both. One of the most  
25 difficult aspects of implementing hyperthermia, with either RF or  
ultrasound waves, is producing sufficient heating at depth.  
Multiple-appliator RF hyperthermia arrays are commonly used to provide a  
focused near-field main beam at the tumor position. Ideally, a focal region

SUBSTITUTE SHEET

should be concentrated at the tumor site with minimal energy delivered to surrounding normal tissue.

In RF hyperthermia systems, the hyperthermia antenna beamwidth is proportional to the RF wavelength in the body. A small focal region suggests that the RF wavelength be as small as possible. However, due to propagation losses in tissue, the RF depth of penetration decreases with increasing transmit frequency. One of the major side-effects in heating a deep-seated tumor with a hyperthermia antenna is the formation of undesired "hot spots" in surrounding tissue. This additional undesired heating often produces pain, burns, and blistering in the patient, which requires terminating the treatment immediately. The patient does not receive anesthetics during the hyperthermia treatment in order to provide direct verbal feedback of any pain. Thus, techniques for reducing hot spots while maximizing energy delivered to the tumor site are desired in hyperthermia treatment.

RF hyperthermia systems with electric field transmitting arrays, i.e., antenna arrays, in the frequency band of 60-2000 Mhz have been used to localize heating of malignant tumors within a target body. Phase control alone of the transmitting antennas of such an array has been used to synthesize therapeutic RF radiation patterns within a target body. Theoretical studies of adaptive control of individual antenna phase and power (transmit weights) has been used to maximize the tumor temperature (or RF power delivered to the tumor) while minimizing the surrounding tissue temperature (or RF power delivered to the surrounding tissue). Invasive temperature measuring techniques have been used to optimize the radiation pattern within a target body.

One commercially available hyperthermia annular phased-array antenna system is the Model BSD-2000, SIGMA-60 applicator, available from BSD Medical Corporation, Salt Lake City, Utah. This phased-array system fully surrounds the patient, placing the patient at the center of an annular array of dipole transmit antennas. By fully surrounding the patient with an annular phased-array, it is possible to obtain constructive

**SUBSTITUTE SHEET**

interference (or signal enhancement) deep within the target volume. This hyperthermia system uses a 60 cm array diameter with eight uniformly spaced dipole elements operating over the frequency band 60-120 MHz. The eight dipoles are fed as four active pairs of elements. There are four  
5 high-power amplifiers which drive the dipole pairs with up to 500 W average power per channel. Each of the four active channels has an electronically controlled variable-phase shifter for focusing the array. Temperature and electric-field probe sensors (both invasive and non-invasive) are used to monitor the treatment. A cool-water (5-40°C) bolus  
10 between the patient and the phased-array is used to prevent excess heating of the skin surface. The water bolus is filled with circulating distilled water, which has a very low propagation loss.

#### SUMMARY OF THE INVENTION

In accordance with the invention, adaptive nulling and/or focusing  
15 with non-invasive auxiliary probes is used to reduce or enhance the field intensity at selected positions in and around the target body while maintaining a desired focus at a tumor thereby avoiding or reducing the occurrences of "hot spots" while enhancing heating of the tumor during ultrasonic or R.F. hyperthermia treatment.

20 In general, in one aspect, the invention features a hyperthermia applicator having electric field radiators each coupled to a source of electric radiation through a controllable transmit weighting network to control the phase and amplitude of the electric field radiation transmitted by each radiator. The transmit weighting networks respond to feedback  
25 signals from a controller coupled to electric field probes which receive the electric field radiation from the radiators. The controller adjusts the feedback signals in response to the received electric field radiation so that the electric field radiation is minimized at the electric field probes.

30 Preferred embodiments include a phased array of electric field radiators, and an annular array of electric field radiators for surrounding the target.

SUBSTITUTE SHEET

The electric field probes include probes placed non-invasively around the perimeter of the target where the electric field energy is to be minimized. In one embodiment, the target is modeled as an ellipse and the electric field probes are placed at the front, back, and on both sides of the ellipse.

5 In another aspect, the invention also features a secondary electric field probe, and the controller adjusts the feedback signals in response to the electric field radiation received by the secondary electric field probe so that the electric field radiation is maximized at the secondary probe.

Embodiments include placing the secondary probe at the desired focus of  
10 the electric field radiation.

In yet another aspect, the invention features the controller performing either a matrix inversion algorithm or a gradient search algorithm to adjust the feedback signals controlling the transmit weighting networks in response to the electric field energy received by the electric  
15 field probes.

In general, in another aspect, the invention features a hyperthermia applicator for heating a target inside a body, having electric field radiators each coupled to a source of electric radiation through a controllable transmit weighting network to control the phase and amplitude of the  
20 electric field radiation transmitted by each radiator. The transmit weighting networks respond to feedback signals from a controller coupled to electric field probes placed outside the body which receive the electric field radiation from the radiators. The controller adjusts the feedback signals in response to the electric field radiation received outside the body  
25 so that the electric field radiation is controlled at the target inside the body.

Preferred embodiments include a phased-array of electric field radiators, an annular array of electric field radiators for surrounding the target, and an array of monopole antenna elements for positioning nearby  
30 the target.

In preferred embodiments of the monopole array, the monopole antenna elements are perpendicularly mounted to one side of an RF

SUBSTITUTE SHEET

reflecting groundplane. An RF reflecting screen is mounted perpendicular to the groundplane surface behind the monopole antenna elements to reflect RF energy from the monopole antenna elements toward the target. The ground plane includes an aperture for positioning the target on the same side of the ground plane as the monopole antenna elements. An enclosure surrounds the monopole antenna elements and provides a vessel for enclosing a bolus of fluid, such as deionized water, between the monopole antenna elements and the body. In other preferred embodiments another ground plane is provided above the monopole antenna elements to form a waveguide between the antenna elements and the target body. Further, multiple waveguides and monopole antenna arrays can be stacked.

In other preferred embodiments of the monopole array, the monopole array antenna elements resonate between 800 and 1000 MHz and are arranged in a circular arc having a radius of between 5 and 20 cm. The body is a cranium and the target is a brain tumor. The radius of the monopole array circular arc is either the distance from the monopole antenna array to the center of the cranium, or to the target tumor.

In still other preferred embodiments, the electric field probes are non-invasively placed along the perimeter of the body between the elements of the phased-array and the target. The controller adjusts the feedback signal, with a gradient search or matrix inversion algorithm, to minimize the difference in the electric field detected by adjacent electric field probes and thereby provide uniform electric field radiation into the body.

In yet other preferred embodiments, the electric field probes are formed into an array non-invasively placed between the phased array and the target. The controller adjusts the feedback signal, with a gradient search or matrix inversion algorithm, to provide a particular electric field pattern across the electric field probe array and thereby focus radiation into the target. The electric field probe array elements are placed symmetrically with respect to a bisector line which runs from the target to

SUBSTITUTE SHEET

the phased array to bisect the phased array. The controller adjusts the feedback signal to balance the electric field pattern with respect to the bisector line, and to minimize the difference in the electric field detected along the bisector line.

5        Thus, the present invention offers the advantages of allowing effective hyperthermia treatment to be applied to deep-seated tumors within the body while reducing or eliminating hot-spot formation on the surface of the body which interferes with the treatment. Another advantage is that hot spots are eliminated quickly by sensing and adjusting  
10    the E-field radiation in the vicinity of the expected hot spot rather than by measuring the temperature rise of the tissue after heating has already occurred. Still another advantage is that the E-field sensing probes may be located on the surface of the target rather than having to be invasively placed within the target body. A further advantage is that the E-field  
15    radiation can be focused on a target inside a body using E-field sensing probes non-invasively placed outside the body to maximize heating of the target tissue.

#### BRIEF DESCRIPTION OF THE DRAWINGS

The foregoing and other objects, features and advantages of the  
20    invention will be apparent from the following more particular description of preferred embodiments of the invention, as illustrated in the accompanying drawings in which like reference characters refer to the same parts throughout different views. The drawings are not necessarily to scale, emphasis instead being placed upon illustrating the principles of the  
25    invention.

FIG. 59 shows a cross-sectional view of another alternative embodiment of the waveguide of FIG. 58A having multiple stacked monopole phased array antennas and associated stacked waveguides.

FIG. 60 is a block diagram of a microwave transmit and receive module for use with the monopole phased array system of FIG. 47.

SUBSTITUTE SHEET

**DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT****Apparatus**

Referring to FIG. 1, there is shown a hyperthermia annular phased-array system 100 having improved "hot spot" characteristics achieved by utilizing the focused near-field adaptive nulling apparatus of this invention. An annular hyperthermia phased-array applicator 102, energized by a hyperthermia array controller 101, has a plurality of dipole transmit antenna elements 104 placed around a patient to be treated, or target body 106. The dipole antenna elements are uniformly disposed around the patient. Each dipole antenna element is oriented parallel to the other dipole antennas and parallel to a longitudinal axis A-A passing through the center of a cylinder defined by applicator 102. The patient is positioned within the hyperthermia phased array applicator 102 such that the deep-seated tumor to be treated 107 is at the approximate center, or focus, of the phased array applicator. A water-bolus 105 is provided between the patient and the phased array applicator to control the temperature of the patient's skin. Phased-array applicator 102 therapeutically illuminates the target body 106 with electric field (E-field) energy radiated by dipole antenna elements 104 focused on tumor 107 deep within the body.

An example of a deep-seated tumor is cancer of the prostate. The tumor volume often has a decreased blood flow which aids in heating the tumor, compared to normal tissue for which heat is carried away by normal blood flow. In practice, undesired high-temperature regions away from the focus can also occur on the skin and inside the volume of the target body. For example, scar tissue, which has a decreased blood flow rate, will tend to heat up more rapidly than normal tissue having normal blood flow.

In the adaptive hyperthermia array of this invention, electric-field nulls are used to reduce the power delivered to potential hot spots. Computer simulations, described herein, establish that non-invasive field probes, or sensors, 112 placed on the surface of the target can be used to eliminate hot spots interior to the target tissue. With the adaptive

**SUBSTITUTE SHEET**

hyperthermia phased-array described herein, RF energy nulls are adaptively formed to reduce the electric field energy delivered to these potential hot spots. As will be shown, the energy nulls achieved by the adaptive nulling apparatus of this invention are both invasive to the target, i.e., extend into the target body, and non-invasive to the target, i.e., on the surface of the target.

Referring to FIG. 2, there is shown a schematic cross-sectional representation of an embodiment of an eight-element hyperthermia phased-array applicator 102 of FIG. 1. Phased-array applicator 102 has transmit antennas 104<sub>1</sub> through 104<sub>8</sub>, arranged symmetrically surrounding a human body target 106' at the prostate level.

An analytical model of the embodiment of FIG. 2 is shown in FIG. 3. Here, an elliptical phantom target 106 is used to model the prostate-level cross section of the human body 106'. The center 107 of the elliptical phantom models the location of the prostate tumor to receive hyperthermia treatment, i.e., the focus of RF energy for the phased array applicator 102. Water bolus 105 is assumed to surround the target body 106, and is treated as a homogeneous medium for analysis purposes.

Four auxiliary RF E-field probes, or sensors, 112<sub>1</sub> through 112<sub>4</sub>, i.e., receiving antennas, are placed around the perimeter of the target to model non-invasive probes placed on the skin of the human body target. Each auxiliary probe 112<sub>1</sub> through 112<sub>4</sub> has a corresponding null zone 120<sub>1</sub> through 120<sub>4</sub>, respectively, centered at each auxiliary probe and extending into the elliptical target region 106. Each null zone indicates an area in which undesired "hot spots" are reduced or eliminated. The width of each null zone is directly related to the strength of each null. The strength of each null (sometimes referred to as the amount of cancellation) is directly related to the signal-to-noise ratio at the probe position ( $SNR_p$ ). A low  $SNR_p$  indicates a large amount of nulling (strong null), and a high  $SNR_p$  indicates a small amount of nulling (weak null). The resolution, or minimum spacing, between the focus 107 and any null position is normally equal to the half-power beamwidth of the transmit antenna. Resolution

**SUBSTITUTE SHEET**

may be enhanced somewhat by using weak nulls whenever the separation between the null and focus is closer than the half-power beamwidth.

Referring to FIG. 4, there is shown the results of a simulation of the thermal distribution inside the target body 106 for the hyperthermia ring array applicator 102 of the analytical model of FIG. 3, without adaptive nulling, transmitting into the target body. For simulation purposes, target body 106 is assumed to be a homogeneous elliptical region, and the RF energy from the array is focused at the center of the ellipse 107, simulating the tumor site. No adaptive nulling is used. The contour lines of the thermal distribution represent isotherms having the indicated temperature in degrees Celsius ( $^{\circ}\text{C}$ ), and are spaced at  $2^{\circ}\text{C}$  intervals. The simulation shows that the focus is expected to have a temperature of approximately  $46^{\circ}\text{C}$ , while two undesired "hot spots" 122 and 124 to the left and right of the focus, respectively, are expected to have temperatures of approximately  $42^{\circ}\text{C}$ .

FIG. 5 shows a simulated thermal distribution for the model of FIG. 3 where the adaptive nulling methods of this invention are applied. Comparison of FIG. 5 with FIG. 4 show that the "hot spots" 122 and 124 are essentially eliminated, no new "hot spots" have been produced within the target body, and the peak temperature induced at the focus is still approximately  $46^{\circ}\text{C}$ .

Referring to FIG. 6, a generalized schematic of the non-invasive adaptive-nulling hyperthermia system of FIG. 3 includes hyperthermia transmitting phased array applicator 102 having a plurality of transmitting antenna elements  $104_n$ , where  $n = 1, \dots, N$ , surrounding target body 106 for focusing RF energy at focus 107 within the target body. Phased array applicator 102 is energized by an RF energy source 108 which is distributed to and drives each transmit antenna element  $104_n$  through a corresponding transmit weighting function  $110_n$ , each having a corresponding weight  $w_n$ . Each weighting function  $w_n$  may affect the gain and phase of the RF energy fed to its corresponding antenna  $104_n$  in the array, i.e.,  $w_n$  represents a complex weighting function. Each weighting

SUBSTITUTE SHEET

-14-

function 110<sub>n</sub> may be implemented by a voltage controlled RF amplifier and a voltage controlled RF phase shifter. An amplitude control voltage representing the amplitude component of transmit weight  $w_n$  is fed to the voltage controlled amplifier, and a phase control voltage representing the phase of transmit weight  $w_n$  is fed to the voltage controlled phase shifter.

Target body 106 has a plurality of E-field auxiliary probes 112<sub>m</sub>, where  $m=1, \dots, N_{aux}$ , i.e., receiving antennas, positioned at various locations on the surface of the body for sampling the E-field at each particular location. Another receiving probe 115 may be placed at the desired focus 107 of the array.

Receiving probes 112<sub>m</sub> and 115 each drive an input to an RF receiver 114. The transmit amplitude and phase weights of each weighting function  $w_n$  are fed to the receiver 114 through lines 103<sub>n</sub> and are used to find the transmit level of each transmit element 104<sub>n</sub>. The outputs of receiver 114 represent the auxiliary probe-received complex voltages  $v_1, v_2, \dots, v_{N_{aux}}$ , the focus probe-received complex voltage  $v_F$ , and the transmit level of the phased array. The receiver outputs drive the inputs of a signal processor 116, which applies a nulling algorithm to adjust the weighting functions  $w_n$  and thereby null, or minimize, the RF signal received by each receiving probe 112<sub>m</sub>, i.e., minimize the  $SNR_p$  at each probe.

To generate the desired field distribution in a clinical adaptive hyperthermia system, the receiving probes are positioned as close as possible to the focus (tumor site) and to where high temperatures are to be avoided (such as near the spinal cord and scar tissue). For an annular array configuration the receiving probes can be located non-invasively on the surface (skin) of the target. Initially, the hyperthermia array is focused to produce the required field intensity at the tumor. An invasive probe may be used to achieve the optimum focus at depth. To avoid undesired hot spots, it is necessary to minimize the power received at the desired null positions and to constrain the array transmit weights  $w_n$  to deliver a required amount of transmitted or focal region power.

SUBSTITUTE SHEET

-15-

Signal processor 116 performs either a sample matrix inversion (SMI) algorithm or a gradient search algorithm on the signals output from receiver 114 and updates the adaptive array weights  $w_n$  (with gain  $g$  and phase  $\phi$ ) to rapidly (within seconds) form the nulls at the auxiliary probes  
5 before a significant amount of target heating takes place. With this adaptive system, it is possible to avoid unintentional hot spots in the proximity of the auxiliary probes and maintain a therapeutic thermal dose distribution at the focus (tumor).

Signal processor 116 may also perform a maximizing algorithm to  
10 maximize energy at the focus 107. The focus probe 115 is invasively placed at the desired focus 107, and used to generate a maximum signal, or signal-to-noise ratio ( $SNR_F$ ), at the tumor site. RF receiver 114 makes an amplitude and phase measurement on the output signal from invasive probe 115 for each transmit antenna element  $104_n$  radiating one at a time.  
15 Signal processor 116 processes these measurements and feeds back weight command signals to the transmit weighting functions  $110_n$  to calibrate or phase align the transmit channels to thereby maximize the  $SNR_F$ , or RF power, at the invasive focal point probe. If receiver 114 makes amplitude-only measurements from invasive focus probe 115, then  
20 a gradient search technique may be applied by the signal processor with all elements transmitting simultaneously to maximize the  $SNR_F$  at the invasive focal point probe.

#### Theoretical Formulation of Nulling Algorithms

FIG. 7 shows an analytical model of a hyperthermia phased-array  
25 antenna system 200, paralleling the generalized hyperthermia phased-array antenna system 100 of FIG. 6, illustrating the principles of the near-field adaptive nulling technique of this invention. The phased-array antenna system 200 includes a hyperthermia transmitting antenna array 202 having a plurality of transmitting antennas  $204_n$ , where  $n = 1, \dots, N$  for  
30 focusing RF energy at a desired focus 207 in the near field of the antenna. Antenna array 202 is energized by an RF energy source 208 which drives a power divider 209. Power divider 209 has one output for driving each

SUBSTITUTE SHEET

antenna 204<sub>n</sub> a corresponding transmit weighting function 210<sub>n</sub>, each having a corresponding transmit weight  $w_n$ . It is assumed here that each weighting function  $w_n$  may affect the phase of the RF energy fed to its corresponding antenna 204<sub>n</sub> in the array. A calibration E-field probe 212, or focus probe antenna, is positioned at focus 207 for sampling the E-field at that location.

It is assumed that the hyperthermia phased-array antenna 200 is focused (as it normally is) in the near field and that a main beam 220 and possibly sidelobes 222 are formed in the target. In general, phase and amplitude focusing is possible. It is assumed that phase focusing alone is used to produce the desired quiescent main beam, i.e., weighting functions  $w_n$  affects only the phase of the RF signal driving each antenna. The signal received by the calibration probe can be maximized by adjusting the phase weighting functions  $w_n$  so that the observed transmit antenna element-to-element phase variation is removed, i.e., all transmit antennas appear to be in-phase when observed from the focus.

One way to achieve phase coherence at the focus in a numerical simulation is to choose a reference path length as the distance from the focus to the phase center 224 of the array. This distance is denoted  $r_F$  and the distance from the focus to the  $n$ th array transmit antenna element is denoted  $r_n^F$ . The voltage received at the calibration probe 212 (located at focus 207) due to the  $n$ th array element may be computed using the "method of moments", as described below. To maximize the received voltage at the calibration probe output, it is necessary to apply the phase conjugate of the signal observed at the calibration probe, due to each array transmit antenna element, to the corresponding element at the transmit array. The resulting near-field radiation pattern will have a main beam and sidelobes. The main beam will be pointed at the array focal point, and sidelobes will exist at angles away from the main beam. Auxiliary probes can then be placed at the desired null positions in the quiescent sidelobe region. These sidelobes occur where tissue hot spots

SUBSTITUTE SHEET

are likely to occur, and they are nulled by one of the adaptive nulling algorithms described below.

#### Adaptive Transmit Array Formulation

Considering again the hyperthermia array and probe geometry shown in FIG. 7, the hyperthermia transmit antenna array 202 typically contains  $N$  identical transmit antenna elements 204. The number of adaptive channels is denoted  $M$ , and for a fully adaptive array  $M=N$ . The ideal transmit weights  $w_n$  (a complex voltage gain vector) are assumed in the computer simulation, with  $\mathbf{w} = (w_1, w_2, \dots, w_N)^T$  denoting the adaptive channel weight vector as shown in FIG. 6. (Superscript T means transpose). To generate adaptive nulls, the transmit weights (phase and gain) are controlled by either the Sample Matrix Inversion (SMI) algorithm or a gradient search algorithm. The SMI algorithm has the flexibility to operate in either open- or closed-loop feedback modes; the gradient search algorithm operates only in a feedback mode.

#### Sample Matrix Inversion (SMI) Algorithm

For the SMI algorithm, the fundamental quantities required to fully characterize the incident field for adaptive nulling purposes are the adaptive channel cross correlations. To implement this algorithm it is necessary to know the complex received voltage at each of the auxiliary probes. For example, the moment-method formulation (described below) allows computation of complex-received voltage at each of the auxiliary probes.

FIG. 8 is a block diagram showing the SMI algorithm applied to the adaptive hyperthermia phased-array of FIG. 7, and the derivation of performance measures to quantify computer simulation results. Four performance measures are used to quantify the computer simulations: electric-field distribution  $E(x, y, z)$ , channel correlation matrix eigenvalues  $\lambda_k$ ,  $k = 1, \dots, N$ , adaptive transmit weights  $w_n$ , and interference cancellation C. The calculation of these performance measures is described in detail below.

SUBSTITUTE SHEET

Assuming a spherical wavefront is incident at an  $i$ th probe antenna 226 due to each of the  $N$  array transmit antenna elements 204 <sub>$n$</sub>  (radiating one at a time with a unity-amplitude reference signal), the result is a set of probe-received complex voltages denoted  $v_1^i, v_2^i, \dots, v_N^i$  after a gain 5 adjustment 250. The cross correlation  $R_{mn}^i$  of the received voltages due to the  $m$ th and  $n$ th transmit antenna (adaptive transmit channel) at the  $i$ th probe is given by

$$R_{mn}^i = E(v_m v_n^*) \quad , \quad (1)$$

where  $*$  means complex conjugate and  $E(\cdot)$  means mathematical expectation. (Note: for convenience, in Equation (1) the superscript  $i$  in  $v_m$  and in  $v_n$  has been omitted.) Because  $v_m$  and  $v_n$  represent voltages of the 10 same waveform but at different times,  $R_{mn}^i$  is also referred to as an autocorrelation function.

In the frequency domain, assuming the transmit waveform has a band-limited white noise power spectral density (as commonly assumed in 15 radar system analysis), Equation (1) can be expressed as the frequency average

$$R_{mn}^i = \frac{1}{B} \int_{f_1}^{f_2} v_m(f) v_n^*(f) df \quad , \quad (2)$$

where  $B = f_2 - f_1$  is the nulling bandwidth, or bandwidth of frequencies applied by the hyperthermia treatment, and  $f$  is the transmit frequency of the hyperthermia array. It should be noted that  $v_m(f)$  takes into account 20 the transmit wavefront shape, which is spherical for the hyperthermia application. For the special case of a continuous wave (CW) transmit waveform, as normally used in hyperthermia, the cross correlation reduces to

SUBSTITUTE SHEET

$$R_{mn}^I = v_m(f_o) v_n^*(f_o) \quad (3)$$

where  $f_o$  is the transmit frequency of the hyperthermia array.

Next, the channel correlation matrix, or interference covariance matrix, denoted  $R$  is determined 252. (Note: in hyperthermia, interference is used to refer to the signals received at the auxiliary probes. The undesired "hot spots" can be thought of as interfering with the therapy.) If there are  $N_{aux}$  independent desired null positions or auxiliary probes, the  $N_{aux}$ -probe channel correlation matrix is the sum of the channel correlation matrices observed at the individual probes. That is,

$$R = \sum_{i=1}^{N_{aux}} R_i + I \quad (4)$$

10 where  $R_i$  is the sample channel correlation matrix observed at the  $i$ th probe and  $I$  is the identity matrix used to represent the thermal noise level of the receiver for simulation purposes.

Prior to generating an adaptive null, the adaptive channel weight vector,  $w$ , is chosen to synthesize a desired quiescent radiation pattern.

15 When nulling is desired, the optimum set of transmit weights to form an adaptive null (or nulls), denoted  $w_a$ , is computed 254 by

$$w_a = R^{-1} w_q \quad (5)$$

where  $^{-1}$  means inverse and  $w_q$  is the quiescent weight vector. During array calibration, the normalized quiescent transmit weight vector, with

SUBSTITUTE SHEET

transmit element 204<sub>1</sub> radiating, is chosen to be  $w_q = (1, 0, 0, \dots, 0)^T$ , i.e., the transmit channel weight of element 204<sub>1</sub> is unity and the remaining transmit channel weights are zero. Similar weight settings are used to calibrate the remaining transmit elements. For a fully adaptive annular array focused at the origin in homogeneous tissue, the normalized quiescent weight vector is simply  $w_q = (1, 1, 1, \dots, 1)^T$ . Commonly, the weight vector is constrained to deliver a required amount of power to the hyperthermia array or to the tumor. For simplicity in the computer simulation used to analyze the hyperthermia array, the weights are

5 constrained such that

10

$$\sum_{n=1}^N |w_n|^2 = 1 \quad , \quad (6)$$

where  $w_n$  is the transmit weight for the  $n$ th element. It should be noted that in the computer simulations, the electric field due to the normalized weight vector is scaled appropriately to deliver the required amount of power to the tissue so that a desired focal-region temperature level is

15 achieved after  $t$  minutes. The summation of power received at the probes is given by

$$p = w^\dagger R w \quad , \quad (7)$$

where  $^\dagger$  means complex conjugate transpose. The signal-plus-noise-to-noise ratio for the auxiliary probe array, denoted  $SNR_p$ , is computed as the ratio of the auxiliary probe array output power (defined in Equation (7)) with the transmit signal present, to the probe array output power with only receiver noise present, that is,

20

SUBSTITUTE SHEET

-21-

$$INR = \frac{w^{\dagger} R w}{w^{\dagger} w} \quad (8)$$

Next, the adaptive array cancellation ratio indicative of the null strength, denoted  $C$ , is determined 255.  $C$  is defined here as the ratio of the summation of probe-received power after adaptation to the summation of probe-received power before adaptation (quiescent); that is,

$$C = \frac{P_a}{P_q} \quad (9)$$

- 5 A large amount of cancellation indicated by a large value for  $C$  indicates a strong null, while a small amount of cancellation indicated by a small value for  $C$  indicates a weak null. Substituting Equation (7) into Equation (9) yields

$$C = \frac{w_a^{\dagger} R w_a}{w_q^{\dagger} R w_q} \quad (10)$$

- 10 Next, the channel correlation matrix defined by the elements in Equations (2) or (3) is Hermitian (that is,  $R = R^{\dagger}$ ), which, by the spectral theorem, can be decomposed 256 in eigenspace as

$$R = \sum_{k=1}^M \lambda_k e_k e_k^{\dagger} \quad (11)$$

- where  $\lambda_k$ ,  $k = 1, 2, \dots, M$  are the eigenvalues of  $R$ , and  $e_k$ ,  $k = 1, 2, \dots, M$  are the associated eigenvectors of  $R$ . The channel correlation matrix  
 15 eigenvalues ( $\lambda_1, \lambda_2, \dots, \lambda_M$ ) are a convenient quantitative measure of the use of the adaptive array degrees of freedom. The amplitude spread between the largest and smallest eigenvalues is a quantitative measure of

SUBSTITUTE SHEET

-22-

the dynamic range of the interference (hot spot) signals. FIG. 9 is a block diagram of the sample matrix inversion algorithm implemented by the signal processor 116 of FIG. 6. Receiver 114 generates probe-received complex voltage vector  $v_1^i, v_2^i, \dots, v_N^i$  for the  $i$ th auxiliary probe. The signal processor generates the transmit channel correlations  $R_{mn}^i$  defined by equation (3), and sums them to form the channel correlation matrix  $R$  defined by equation (4). Next, the signal processor multiplies the inverse of the channel correlation matrix  $R^{-1}$  by the quiescent transmit weight vector  $w_q$  to form the new adapted transmit weight vector  $w_a$ , containing the adapted transmit weights fed back to the transmit weight networks 110<sub>n</sub> of FIG. 6.

#### Gradient Search Algorithm

Under conditions where only the probe received voltage amplitude is measured, it is appropriate to consider a gradient search algorithm to minimize the interference power at selected positions. The gradient search is used to control the transmit weights  $w_n$  iteratively such that the RF signal received by the probe array is minimized. The transmit array weights (gain and phase) are adaptively changed in small increments and the probe array output power is monitored to determine weight settings that reduce the output power most rapidly to a null.

Consider  $J$  sets of  $N$  transmit weights that are applied to adaptive hyperthermia phased array applicator 102 of FIG. 6. In terms of adaptive nulling, the optimum transmit weight settings (from the collection of  $J$  sets of  $N$  transmit weights) occur when the  $SNR_p$  is minimized. Equivalently, the total interference power received by the auxiliary probe array, denoted  $p^{rec}$ , is to be minimized. For notational convenience let a figure of merit  $F$  denote either the  $SNR_p$  or  $p^{rec}$  and employ a gradient search to find the optimum transmit weights to minimize  $F$ , that is,

$$F_{opt} = \min(F) \quad j=1,2,\dots,J \quad (12)$$

SUBSTITUTE SHEET

-23-

The transmit weight settings for which  $F_{opt}$  occurs yields the closest approximation to the optimal transmit weights determined by using the sample matrix inverse approach described above.

FIG. 10 shows an amplitude and phase scatter diagram for the  $N$  complex transmit weights  $w_n$  at the  $j$ th configuration, i.e., the  $j$ th set of weights tried. The  $n$ th transmit weight in the  $j$ th configuration of transmit weights is denoted

$$w_n = A_n e^{j\Phi_n} \quad (13)$$

where  $A_{nj}$  is the transmit weight amplitude distributed over the range  $A_{min}$  to  $A_{max}$  and  $\Phi_{nj}$  is the transmit weight phase distributed over the range  $-\pi$  to  $\pi$  radians.

Referring also to FIG. 11, it is desired to find the values of amplitude and phase for each of the  $N$  transmit weights such that the figure of merit  $F$  ( $SNR_p$  or  $p^{rec}$ ) is minimized. When the figure of merit is minimized, adaptive radiation pattern nulls will be formed at the auxiliary probe positions.

Assuming an initial setting of the  $N$  transmit weights such as those selected to focus the radiation pattern on a tumor, the weights are adjusted by dithering them until the optimum figure of merit is achieved. It is desired to find the collective search directions for the  $N$  transmit weights such that  $F$  decreases most rapidly. That is, weights are selected so that the directional derivative is minimized at  $(A_j, \Phi_j)$ , where  $A_j$  and  $\Phi_j$  are vectors representing the transmit amplitude weights and transmit phase weights, respectively, for the  $j$ th configuration.

The directional derivative of  $F_j$  is expressed in terms of the amplitude and phase changes of the transmit weights as

SUBSTITUTE SHEET

-24-

$$D(F_j) = \sum_{n=1}^N \left( \frac{\partial F_j}{\partial A_n} r_{An} + \frac{\partial F_j}{\partial \Phi_n} r_{\Phi n} \right) \quad (14)$$

where  $\partial$  means partial derivative, and  $r_{An}$ ,  $r_{\Phi n}$  are the  $(A, \Phi)$  directions for which  $F_j$  is decreasing most rapidly. The directions  $r_{An}$ ,  $r_{\Phi n}$  are constrained by

$$\sum_{n=1}^N (r_{An}^2 + r_{\Phi n}^2) = 1 \quad (15)$$

It is desired to minimize  $D(F_j)$  subject to the above constraint equation.

- 5 Using Lagrange multipliers it is possible to construct the Lagrangian function

$$L_j = \sum_{n=1}^N \left( \frac{\partial F_j}{\partial A_n} r_{An} + \frac{\partial F_j}{\partial \Phi_n} r_{\Phi n} \right) + G \left[ 1 - \sum_{n=1}^N (r_{An}^2 + r_{\Phi n}^2) \right] \quad (16)$$

where  $G$  is a constant to be determined. The requirement that  $L_j$  be an extremum implies

$$\frac{\partial L_j}{\partial r_{An}} = \frac{\partial F_j}{\partial A_n} - 2Gr_{An} = 0, n=1, 2, \dots, N \quad (17)$$

and

$$\frac{\partial L_j}{\partial r_{\Phi n}} = \frac{\partial F_j}{\partial \Phi_n} - 2Gr_{\Phi n} = 0, n=1, 2, \dots, N \quad (18)$$

10 or that

SUBSTITUTE SHEET

-25-

$$r_{A_n} = \frac{1}{2G} \frac{\partial F_I}{\partial A_n} \quad (19)$$

and

$$r_{\Phi_n} = \frac{1}{2G} \frac{\partial F_I}{\partial \Phi_n} \quad (20)$$

Squaring equations (19) and (20) and invoking equation (15) yields:

$$\sum_{n=1}^N (r_{A_n}^2 + r_{\Phi_n}^2) = 1 = \frac{1}{4G^2} \sum_{n=1}^N \left[ \left( \frac{\partial F_I}{\partial A_n} \right)^2 + \left( \frac{\partial F_I}{\partial \Phi_n} \right)^2 \right] \quad (21)$$

thus,

$$G = \pm \frac{1}{2} \sqrt{\sum_{n=1}^N \left[ \left( \frac{\partial F_I}{\partial A_n} \right)^2 + \left( \frac{\partial F_I}{\partial \Phi_n} \right)^2 \right]} \quad (22)$$

SUBSTITUTE SHEET

Substituting this expression for G in equations (19) and (20) gives

$$r_{A_n} = - \frac{\frac{\partial F_I}{\partial A_n}}{\sqrt{\sum_{n=1}^N \left[ \left( \frac{\partial F_I}{\partial A_n} \right)^2 + \left( \frac{\partial F_I}{\partial \Phi_n} \right)^2 \right]}} \quad (23)$$

and

$$r_{\Phi_n} = - \frac{\frac{\partial F_I}{\partial \Phi_n}}{\sqrt{\sum_{n=1}^N \left[ \left( \frac{\partial F_I}{\partial A_n} \right)^2 + \left( \frac{\partial F_I}{\partial \Phi_n} \right)^2 \right]}} \quad (24)$$

- The minus sign was chosen corresponding to the direction of maximum function decrease. This choice of minus sign in equation (22) enforces
- 5 nulls in the hyperthermia array radiation pattern. Alternatively, if the positive sign in equation (22) is selected, then the gradient directions can be used to maximize the figure of merit for the purposes of focusing at an invasive probe at the tumor site, i.e., maximize the  $SNR_F$ . This may be used, for example, to determine the quiescent transmit weight vector  $w_q$ .
- 10 Thus, two gradient searches may be performed to optimize the radiation pattern of the hyperthermia array. The first to produce a peak or focused radiation pattern at the tumor, and the second to form the desired nulls at the auxiliary probes. Furthermore, these two gradient searches may be implemented as a single, combined gradient search constrained to
- 15 maximize the radiation pattern at the focus and minimize the radiation pattern at the desired nulls. The combined gradient search is implemented by minimizing the figure of merit defined as the ratio of the power received at the auxiliary probes to the power received by the probe at the focus.

**SUBSTITUTE SHEET**

The partial derivatives

$$\frac{\partial F_j}{\partial A_n}, \frac{\partial F_j}{\partial \Phi_n}; n=1,2,\dots,N \quad (25)$$

represent the gradient directions for maximum function decrease. Since the figure of merit  $F$  cannot be expressed here in analytical form, the partial derivatives are numerically evaluated by using finite differences.

5 Thus, we write

$$\frac{\partial F_j}{\partial A_n} = \frac{\Delta F_{Aj}}{2\Delta A_n} \quad (26)$$

and

$$\frac{\partial F_j}{\partial \Phi_n} = \frac{\Delta F_{\Phi j}}{2\Delta \Phi_n} \quad (27)$$

where as shown in FIG. 2 the figure of merit differences are

$$\Delta F_{Aj} = F_j(A_n + \Delta A_n; \Phi_n) - F_j(A_n - \Delta A_n; \Phi_n) \quad (28)$$

and

$$\Delta F_{\Phi j} = F_j(A_n; \Phi_n + \Delta \Phi_n) - F_j(A_n; \Phi_n - \Delta \Phi_n) \quad (29)$$

and  $\Delta A_{nj}$  and  $\Delta \Phi_{nj}$  are assumed to be small increments.

- 10 We will assume that the increments  $\Delta A_{nj}$  and  $\Delta \Phi_{nj}$  are independent of the configuration number and element number, that is,

SUBSTITUTE SHEET

-28-

$$\Delta A_n = \Delta A \quad (30)$$

and

$$\Delta \Phi_n = \Delta \Phi \quad (31)$$

Substituting equations (26), (27), (30) and (31) in equations (23) and (24) gives the desired result for the search directions

$$r_{An} = - \frac{\frac{\Delta F_{An}}{\Delta A}}{\sqrt{\sum_{n=1}^N \left[ \left( \frac{\Delta F_{An}}{\Delta A} \right)^2 + \left( \frac{\Delta F_{\Phi n}}{\Delta \Phi} \right)^2 \right]}} \quad (32)$$

5 and

$$r_{\Phi n} = - \frac{\frac{\Delta F_{\Phi n}}{\Delta \Phi}}{\sqrt{\sum_{n=1}^N \left[ \left( \frac{\Delta F_{An}}{\Delta A} \right)^2 + \left( \frac{\Delta F_{\Phi n}}{\Delta \Phi} \right)^2 \right]}} \quad (33)$$

Equations (32) and (33) are used to compute the new amplitude and phase settings of the  $(j+1)$ th transmit weight configuration according to

**SUBSTITUTE SHEET**

$$A_{nj+1} = A_{nj} + \Delta A_{r_{nj}} \quad (34)$$

and

$$\Phi_{nj+1} = \Phi_{nj} + \Delta \Phi_{r_{nj}} \quad (35)$$

In practice, it may be necessary to keep one of the transmit weights fixed (in amplitude and in phase) during the gradient search to guarantee convergence.

- 5 FIG. 12 is a block diagram of the gradient search algorithm implemented by the signal processor 116 of FIG. 6. Each of the N transmit antennas 104<sub>n</sub> of phased array applicator 102 (FIG. 6) is driven through its corresponding weighting network 110<sub>n</sub> which applies complex transmit weights  $w_{nj}$  at the  $j$ th configuration of the weights. The transmit
- 10 antennas induce a voltage across the  $k$ th probe antenna 112<sub>k</sub> at the corresponding input to receiver 114 (FIG. 6). Receiver 114 amplifies the signal received from the  $k$ th probe by gain  $a_k$  to produce voltage amplitude vector  $|v_{1j}^i|, |v_{2j}^i|, \dots, |v_{Nj}^i|$  at the receiver output.
- The voltage amplitude vector is input to signal processor 116 which
- 15 performs the gradient search. For any initial configuration ( $j=1$ ) of the transmit weights  $w_{nj}$ , the signal processor causes each weight to be dithered by a small amount in amplitude,  $\Delta A_{nj}$ , and phase,  $\Delta \Phi_{nj}$ . Each transmit weight is dithered independent of the other transmit weights, which remain in their  $j$ th configuration state. Received voltage vectors
- 20  $|v_{1j}^i|, |v_{2j}^i|, \dots, |v_{Nj}^i|$ , i.e., are stored and used to calculate the resulting figure of merit  $F_{nj}$  300 for each dithered condition, the figure of merit being the power received by the auxiliary probe array. The figure of merit is a rectangular matrix of dimension  $N \times 4$ , where the dimensionality of four is due to the plus and minus dithering of both of the amplitude and
- 25 phase. The figure of merit differences  $\Delta F_{A_{nj}}$  and  $\Delta F_{\Phi_{nj}}$  caused by

SUBSTITUTE SHEET

dithering the amplitude and phase, respectively, are calculated according to equations (28) and (29). The gradient search directions  $r_{Anj}$  and  $r_{\phi nj}$ , based upon minimizing the auxiliary probe array received power, are then determined 302 from the figure of merit differences according to equations 5 (32) and (33), respectively. The resulting search directions are used to update 304 transmit weights  $w_{nj}$  to the  $(j+1)$ th configuration transmit weights  $w_{n,j+1}$  according to equations (34) and (35). The transmit weights  $w_{n,j+1}$  are sent to update the transmit weighting networks 110<sub>n</sub>, and the process is repeated. The final adaptive weight vector  $w_a$  is 10 achieved when the  $(j+1)$ th transmit weight configuration has converged. Convergence is expected to occur within several hundred iterations depending on the dither step size  $\Delta A$  and  $\Delta \phi$ .

It is understood that other forms of gradient searches exist which can be used to update the transmit weights toward convergence. Another 15 such gradient search approach, where the step sizes  $\Delta A$  and  $\Delta \phi$  are computed at each iteration, is described by D.J. Farina and R.P. Flam, "A Self-normalizing Gradient Search Adaptive Array Algorithm", IEEE Transactions on Aerospace and Electronic Systems, November 1991, Vol. 27, No. 6, pp 901-905.

20      COMPUTER SIMULATION OF ADAPTIVE NULLING HYPERTHERMIA  
         Moment-Method Formulation

Referring again to FIG. 8, a method of moments formulation 258 is used to compute the probe-received voltages in Equation (2) due to the transmitting hyperthermia phased-array antenna in an infinite 25 homogeneous conducting medium. The medium is described by the three parameters  $\mu$ ,  $\epsilon$ , and  $\sigma$ , which are discussed below. The formulation given here is analogous to that developed under array-receiving conditions for an adaptive radar. The software used to analyze a hyperthermia array is based on the receive-array analogy but the theory presented below is 30 given in the context of a transmit array.

SUBSTITUTE SHEET

- An antenna analysis code (WIRES) originally developed by J.H. Richmond is capable of analyzing antenna or radar cross section problems. See, J.H. Richmond, "Computer program for thin-wire structures in a homogeneous conducting medium", Ohio State University, ElectroScience Laboratory, Technical Report 2902-12, August 1973; and, J.H. Richmond, "Radiation and scattering by thin-wire structures in a homogeneous conducting medium (computer program description)", IEEE Trans. Antennas Propagation, Vol. AP-22, no. 2, p.365, March 1974. WIRES was modified to analyzing the near-field and far-field adaptive nulling performance of thin-wire phased arrays in free space. A new version of the thin-wire code that can analyze adaptive hyperthermia arrays in an infinite homogeneous conducting medium was written to conduct the adaptive hyperthermia simulation discussed below. The new version of the thin-wire code is attached as Appendix A.
- WIRES is a moment-method code that uses the electric field integral equation (EFIE) to enforce the boundary condition of the tangential electric field being zero at the surface of the antenna of interest. The moment-method basis and testing functions used in this code are piecewise sinusoidal.
- Appendix B lists sample input and output files for the adaptive hyperthermia simulation. The first data file was used to generate the E-field results for a four auxiliary probe system, and the second data file was used to generate the E-field results for a two auxiliary probe system. The corresponding output files give the values for the array mutual coupling, quiescent and adaptive transmit weights, channel correlation matrix, eigenvalues, and cancellation.
- Referring to FIG. 13, there is shown the hyperthermia phased-array antenna system 200 of FIG. 7, redrawn to simplify the following method of moments analysis. The RF source 208, power divider 209 and weights  $210_n$  of FIG. 7, are modeled as a plurality of RF signal generators  $250_1$  through  $250_N$ , feeding its corresponding transmit antenna element  $204_1$  through  $204_N$ . Each generator  $250_1$  through  $250_N$  has a corresponding

SUBSTITUTE SHEET

amplitude and phase weight denoted by  $w_1$  through  $w_N$ , and a known output impedance  $Z_L$ . The  $j$ th probe 226 (i.e., the same as the  $j$ th probe 226 of FIG. 7, with different notation) is modeled as a dipole antenna having an overall length  $L_p$  and an open-circuit voltage  $v_j^{o.c.}$  induced by the RF energy transmitted from the antenna array 200.

The open-circuit voltage at the  $j$ th probe antenna 226 is computed from the array terminal currents and from  $Z_{n,j}^j$ , the open-circuit mutual impedance between the  $n$ th array element and the  $j$ th probe antenna. Let  $v_{n,j}^{o.c.}$  represent the open-circuit voltage at the  $j$ th probe due to the  $n$ th transmit-array element. Here, the  $j$ th probe can denote either the focal point calibration probe (calibration probe 212 of FIG. 7) or one of the auxiliary probes used to null a sidelobe. The number of auxiliary probes is denoted by  $N_{aux}$ .

Referring also to FIG. 14, the  $j$ th probe 226 is modeled as a voltage source 260, having an output voltage  $v_j^{o.c.}$ , driving a first impedance 262, representing the input impedance  $Z_{IN}$  of the  $j$ th probe, in series with a second impedance 264, representing the termination impedance  $Z_r$  of the  $j$ th probe. The  $j$ th probe receive current  $i_j^{rec}$  flows through these two impedances. The output voltage of the  $j$ th probe  $v_j^{rec}$  appears across the termination impedance  $Z_r$ .

Referring again to FIG. 13, next, let  $Z$  denote the open-circuit mutual impedance matrix (with dimensions  $N \times N$  for the  $N$ -element array). The open-circuit mutual impedance between array elements 204<sub>m</sub> and 204<sub>n</sub> is denoted  $Z_{m,n}$ . It is assumed that multiple interaction between the hyperthermia array and the auxiliary probe can be neglected. Thus, the hyperthermia array terminal current vector  $I$  can be computed in terms of the transmit weights  $w$  as

$$I = [Z + Z_L I]^{-1} w \quad (36)$$

SUBSTITUTE SHEET

-33-

Next, let  $Z_{n,j}$  be the open-circuit mutual impedance between the  $j$ th probe and the  $n$ th array element. The induced open-circuit voltage  $v_{n,j}^{o.c.}$  at the  $j$ th receive probe, due to the  $n$ th array element transmit current  $i_n$ , can then be expressed as

$$v_{n,j}^{o.c.} = Z_{n,j} i_n \quad (37)$$

5 In matrix form, the induced open-circuit probe-voltage matrix  $v_{probe}^{o.c.}$  is

$$v_{probe}^{o.c.} = Z_{probe,array} i \quad (38)$$

or

$$v_{probe}^{o.c.} = Z_{probe,array} [Z + Z_L]^{-1} W \quad (39)$$

where  $Z_{probe,array}$  is a rectangular matrix of order  $N_{aux} \times N$  for the open-circuit mutual impedance between the probe array and the hyperthermia array. Note that the  $j$ th row of the matrix  $Z_{probe,array}$  is written as  $(Z_1^j, Z_2^j, \dots, Z_N^j)$ , where  $j = 1, 2, \dots, N_{aux}$ . The receive voltage matrix is then computed by the receiving circuit equivalence theorem for an antenna. The receive-antenna equivalent circuit is depicted in FIG. 14, where it is readily determined that

$$v_{probe}^{rec} = v_{probe}^{o.c.} \frac{Z_r}{Z_n + Z_r} \quad (40)$$

SUBSTITUTE SHEET

-34-

where  $Z_{in}$  is the input impedance of the probe. It should be noted that the  $v_{probe}^{rec}$  matrix is a column vector of length  $N_{aux}$  and  $v_j^{rec}$  is the  $j$ th element of the matrix. The probe-receive current matrix is given by

$$i_{probe}^{rec} = v_{probe}^{a.c.} \frac{1}{Z_h + Z_r} \quad (41)$$

The  $j$ th element of the column vector  $i_{probe}^{rec}$  is denoted  $i_j^{rec}$ ,  $j = 1, 2, \dots, N_{aux}$ . Finally, the power received by the  $j$ th probe is

$$p_j^{rec} = \frac{1}{2} \text{Re}(v_j^{rec} \cdot i_j^{rec*}) \quad (42)$$

where  $\text{Re}$  means real part. Substituting Equations (40) and (41) into Equation (42) yields

$$p_j^{rec} = \frac{1}{2} |v_j^{a.c.}|^2 \frac{\text{Re}(Z_r)}{|Z_h + Z_r|^2} \quad (43)$$

The total interference power received by the auxiliary probe array is given by

10

$$p^{rec} = \sum_{j=1}^{J_{aux}} p_j^{rec} \quad (44)$$

SUBSTITUTE SHEET

-35-

The incident electric field  $E$  is related to the open-circuit voltage  $v^{o.c.}$  by the effective height  $h$  of the probe antenna as

$$v^{ac} = hE \quad (45)$$

If the length  $L_p$  of the probe antenna 226 is approximately  $0.1\lambda$  or less, the current distribution is triangular and the effective height is  $h = 0.5L_p$ .  
 5 Thus, for a short-dipole probe the open-circuit voltage can be expressed as

$$v^{ac} = \frac{L_p}{2} E \quad (46)$$

It then follows from Equation (46) that the  $E$  field for a short-dipole probe at position  $(x, y, z)$  is given by

$$E(x, y, z) = \frac{2v^{ac}(x, y, z)}{L_p} \quad (47)$$

Finally, the quiescent and adapted E-field radiation patterns are computed using the quiescent and adapted weight vectors  $w_q$  and  $w_a$ , respectively,  
 10 in Equations (39) and (47). The moment-method expansion and testing functions are assumed to be sinusoidal. The open-circuit mutual impedances in Equation (39) between thin-wire dipoles in a homogeneous conducting medium are computed based on subroutines from the moment-method computer code developed by J.H. Richmond. In  
 15 evaluating  $Z_n^j$  for the  $j$ th auxiliary probe, double precision computations are used.

SUBSTITUTE SHEET

As mentioned previously, the array is calibrated (phased focused) initially using a short dipole at the focal point. To accomplish this numerically, having computed  $\mathbf{v}_{focus}^{rec}$ , the transmit array weight vector  $\mathbf{w}$  will have its phase commands set equal to the conjugate of the

5 corresponding phases in  $\mathbf{v}_{focus}^{rec}$ . Transmit antenna radiation patterns are obtained by scanning (moving) a dipole probe with half-length  $l$  in the near-field and computing the receive probe-voltage response.

The received voltage matrix for the  $j$ th probe (denoted  $\mathbf{v}_j^{rec}$ ) is computed at  $K$  frequencies across the nulling bandwidth. Thus,

10  $\mathbf{v}_j^{rec}(f_1), \mathbf{v}_j^{rec}(f_2), \dots, \mathbf{v}_j^{rec}(f_K)$  are needed. For the purposes of this computer simulation, the impedance matrix is computed at  $K$  frequencies and is inverted  $K$  times. The probe channel correlation matrix elements are computed by evaluating Equation (2) numerically, using Simpson's rule numerical integration. For multiple auxiliary probes, the channel

15 correlation matrix is evaluated using Equation (4). Adaptive array radiation patterns are computed by superimposing the quiescent radiation pattern with the weighted sum of auxiliary-channel-received voltages.

#### Wave Propagation in Conducting Media

To gain insight into the effect of a lossy medium, e.g., the target

20 body, on the propagation of an electromagnetic wave, it is useful to review certain fundamental equations which govern the field characteristics. In a conducting medium, Maxwell's curl equations in time-harmonic form are

$$\nabla \times \mathbf{H} = \mathbf{J} + j\omega\epsilon\mathbf{E} \quad (48)$$

and

$$\nabla \times \mathbf{E} = -j\omega\mu\mathbf{H} \quad (49)$$

SUBSTITUTE SHEET

-37-

where  $E$  and  $H$  are the electric and magnetic fields, respectively,  $J$  is the conduction current density,  $\omega = 2\pi f$  is the radian frequency,  $\epsilon$  is the permittivity of the medium, and  $\mu$  is the permeability of the medium. The permittivity is expressed as  $\epsilon = \epsilon_r \epsilon_0$ , where  $\epsilon_r$  is the dielectric constant (relative permittivity) and  $\epsilon_0$  is the permittivity of free space. Similarly,  $\mu = \mu_r \mu_0$ , where  $\mu_r$  is the relative permeability and  $\mu_0$  is the permeability of free space. For a medium with electrical conductivity  $\sigma$ ,  $J$  and  $E$  are related as

$$J = \sigma E \quad (50)$$

Substituting Equation (50) into Equation (48) yields

$$\nabla \times H = (\sigma + j\omega\epsilon)E \quad (51)$$

From Equations (48) and (49), the vector wave equation in terms of  $E$  is derived as

$$\nabla^2 E - \gamma^2 E = 0 \quad (52)$$

It is readily shown that

$$\gamma = \pm \sqrt{j\omega\mu(\sigma + j\omega\epsilon)} = \pm j\omega\sqrt{\mu\epsilon} \sqrt{1 - j\frac{\sigma}{\omega\epsilon}} \quad (53)$$

The quantity  $\sigma/\omega\epsilon$  is referred to as the loss tangent. It is common to express the complex propagation constant as

**SUBSTITUTE SHEET**

-38-

$$\gamma = \alpha + j\beta \quad (54)$$

where  $\alpha$  is the attenuation constant and  $\beta$  is the phase constant. The constants  $\alpha$  and  $\beta$  are found by setting Equation (53) equal to Equation (54) and then squaring both sides, equating the real and imaginary parts, and solving the pair of simultaneous equations, with the result

$$\alpha = \frac{\omega\sqrt{\mu\epsilon}}{\sqrt{2}} \left[ \sqrt{1 + \left(\frac{\sigma}{\omega\epsilon}\right)^2} - 1 \right]^{1/2} \quad (55)$$

5 and

$$\beta = \frac{\omega\sqrt{\mu\epsilon}}{\sqrt{2}} \left[ \sqrt{1 + \left(\frac{\sigma}{\omega\epsilon}\right)^2} + 1 \right]^{1/2} \quad (56)$$

The wavelength  $\lambda$  in the lossy dielectric is then computed from

$$\lambda = \frac{2\pi}{\beta} \quad (57)$$

The intrinsic wave impedance  $\eta$  is given by

$$\eta = \sqrt{\frac{j\omega\mu}{\sigma + j\omega\epsilon}} = \sqrt{\frac{\mu}{\epsilon}} \frac{1}{\sqrt{1 - j\frac{\sigma}{\omega\epsilon}}} \quad (58)$$

SUBSTITUTE SHEET

-39-

The instantaneous power density of the electromagnetic field is given by Poynting's vector, denoted  $P$ ,

$$P = \frac{1}{2} E \times H^* \quad (59)$$

which has units of (W/m<sup>2</sup>). The time-average power flow density is equal to the real part of the complex Poynting's vector. The time-average power dissipation per unit volume  $P_d$  (W/m<sup>3</sup>) is derived from Maxwell's equations, with the result

$$P_d = \frac{1}{2} E \cdot J^* = \frac{1}{2} \sigma |E|^2 \quad (60)$$

The specific absorption rate (SAR) is the power dissipated or absorbed per unit mass (W/kg) of the medium (tissue), or

$$SAR = \frac{P_d}{\rho} = \frac{\sigma}{2\rho} |E|^2 \quad (61)$$

where  $\rho$  is the density of the medium in kg/m<sup>3</sup>.

10 It is convenient to have a simple equation for computing the propagation loss between any two points in the near field of an isolated transmitting antenna. Thus, mutual coupling effects are ignored for the time being. Consider a time-harmonic source radiating a spherical wave into an infinite homogeneous conducting medium. For an isotropic

SUBSTITUTE SHEET

-40-

radiator, and suppressing the  $e^{j\omega t}$  time dependence, the electric field as a function of range  $r$  can be expressed as

$$E(r) = E_o \frac{e^{-\gamma r}}{r} \quad (62)$$

where  $E_o$  is a constant.

For a source at the origin, the amplitude of the electric field at range  
5  $r_1$  is given by

$$|E(r_1)| = E_o \frac{e^{-\alpha r_1}}{r_1} \quad (63)$$

and at range  $r_2$  by

$$|E(r_2)| = E_o \frac{e^{-\alpha r_2}}{r_2} \quad (64)$$

The total propagation loss between ranges  $r_1$  and  $r_2$  is found by taking the ratio of Equations (64) and (63), or

$$\frac{|E(r_2)|}{|E(r_1)|} = \frac{r_1}{r_2} e^{-\alpha(r_2 - r_1)} \quad (65)$$

The field attenuation  $A_o$  in dB from range  $r_1$  to range  $r_2$  due to the lossy  
10 dielectric is simply

**SUBSTITUTE SHEET**

-41-

$$A_e = 20 \log_{10} (e^{-\alpha(r_2 - r_1)}) \quad (66)$$

Similarly, the  $1/r$  attenuation loss  $A_r$  in dB is

$$A_r = 20 \log_{10} \frac{r_1}{r_2} \quad (67)$$

#### Thermal Modeling of an Inhomogeneous Target

A thermal analysis computer program called the transient thermal analyzer (TTA), developed by Arthur D. Little, Inc., has been used to  
5 accomplish the thermal modeling of homogeneous muscle tissue surrounded by a constant-temperature water bolus.

The TTA program uses the finite-difference technique to solve a set of nonlinear energy balance equations. Consider a system of interconnected nodes that model an inhomogeneous volume for which the  
10 temperature  $T_i$  of the  $i$ th node is to be determined. The heat-balance equation, which is solved by TTA, is expressed as

$$\sum_{j=1}^N Q_{ij} - P_i(t) + M_i \frac{dT_i}{dt} = 0 \quad (68)$$

where  $Q_{ij}$  is the net outward heat flow from node  $i$  in the direction of node  $j$ ,  $P_i(t)$  is the power into node  $i$  at time  $t$ , and  $M_i$  is the thermal mass (mass times specific heat) of node  $i$ .

15 FIG. 15 shows an electric circuit analog 400 which is used to model the two-dimensional thermal characteristics of the material volume 402 which simulates the target body as a plurality of uniformly distributed nodes 406 spaced  $\Delta l$  apart. With reference to the  $i$ th node 406, but

SUBSTITUTE SHEET

-42-

applying generally to the other nodes, power  $P_i$  in watts is delivered 404<sub>i</sub> to the  $i$ th node. Capacitor 408<sub>i</sub>, having thermal capacitance denoted  $C_i$  (with units Joules/°C), is used to model the thermal capacitance at the  $i$ th node. Resistor 410<sub>ij</sub>, having heat resistance denoted  $R_{i,j}$  (with units  
5 °C/W), is used to model the heat resistance between  $i$ th node 406<sub>i</sub> and the  $j$ th node 406<sub>j</sub>.

With a spacing of  $\Delta l$  between nodes (assuming cubic cells), the values of  $R_{i,j}$ ,  $C_i$  and  $P_i$  are computed as

$$R_{ij} = \frac{1}{k_{ij} \Delta l} \quad (69)$$

where  $k_{ij}$  is the thermal conductivity (with units W/m°C) between nodes  $i$   
10 and  $j$ ;

$$C_i = \rho_i C_{pi} (\Delta l)^3 \quad (70)$$

where  $C_{pi}$  is the specific heat at the  $i$ th node and  $\rho_i$  is the density (kg/m<sup>3</sup>) at the  $i$ th node; and

$$P_i = (SAR)_i \rho_i (\Delta l)^3 \quad (71)$$

where  $(SAR)_i$  is the SAR for the  $i$ th node, which is given by

$$(SAR)_i = \frac{\sigma_i}{2\rho_i} |E_i|^2 \quad (72)$$

SUBSTITUTE SHEET

where  $\sigma_i$  is the electrical conductivity of the  $i$ th node and  $|E_i|$  is the magnitude of the electric field delivered by the hyperthermia array to the  $i$ th node. It should be noted that in substituting Equation (72) into Equation (71), the density  $\rho_i$  cancels. Thus, an equivalent approach to  
5 computing the power delivered to the  $i$ th node is written in terms of the time-average power dissipated per unit volume of the  $i$ th node (denoted  $P_{di}$ ) as

$$P_i = P_d (\Delta)^3 \quad (73)$$

FIG. 16 is a block diagram showing how TTA is used in the hyperthermia simulation described herein. First, the method of moments  
10 500, controlled by the SMI nulling algorithm 502, is used to compute the electric field radiation pattern throughout a homogeneous region, simulating muscle tissue, inside an annular phased array 501. These E-field simulations assume that the signal received by a short-dipole probe within the region is due to a transmitting phased array embedded in an  
15 infinite homogeneous lossy dielectric (muscle tissue).

The resulting E-Field power distribution is then read 504 into the TTA program 506, which computes the temperature distribution inside an elliptical muscle-tissue target surrounded with a constant-temperature water bolus 507. Because the RF wavelengths in the target and water  
20 bolus are similar, the E-field simulations are believed to give a reasonable approximation to the field distribution inside the elliptical target. The computed temperature distribution is output 508 from the TTA for further analysis or display.

The E-field calculation in the assumed infinite homogeneous medium  
25 introduces additional field attenuation not present in a clinical hyperthermia system with an annular array transmitting through a water bolus into a patient. As mentioned earlier, the water bolus has very little RF propagation loss. In addition, the transmit array weights are normalized

SUBSTITUTE SHEET

according to Equation (6). Thus, no attempt is made to compute the absolute E-field strength in volts/meter in the elliptical target. Instead, the peak power in the elliptical target is adjusted (by a scale factor) to produce a desired maximum focal-region temperature ( $T_{max}$ ) after  $t$  minutes. It should be noted that an approximate absolute scale factor could be computed by making an initial computer simulation with an infinite homogeneous water bolus and then matching the target boundary field to the infinite homogeneous muscle tissue simulation.

The computer simulation model is related, in part, to the hyperthermia annular phased-array antenna system shown in FIG. 1. The simulated array is assumed to have a 60-cm array diameter with eight uniformly spaced dipole elements which operate over the frequency band 60-120 MHz. The eight elements of the array are assumed to be fully adaptive, whereby seven independent nulls can be formed while simultaneously focusing on a tumor.

It is further assumed for the purpose of this simulation that the adaptive radiation pattern null-width characteristics in a homogeneous target are similar to the characteristics observed in an inhomogeneous target. The null-width characteristics are directly related to the RF wavelength, and, only a 5 percent change in wavelength occurs between the assumed muscle tissue and water bolus. With this assumption, the transmit array may be simulated as embedded in homogeneous tissue, which allows direct use of the thin-wire moment-method formulation discussed above.

After computing the two-dimensional E-field distribution in the homogeneous medium, we then consider only an elliptical portion of the homogeneous region and use the ellipse as the homogeneous target. In the thermal analysis, the elliptical target is surrounded with a constant 10°C water bolus. The E-field amplitude is scaled to produce a 46°C peak temperature, at time  $t=20$  minutes, at the center of the elliptical phantom. The initial temperature of the phantom is assumed to be 25°C (room temperature).

SUBSTITUTE SHEET

All computer simulations assume a 120 MHz operating frequency with initially four auxiliary nulling probes, i.e.,  $N_{aux}=4$ . The parameters used in the electrical and thermal analyses are summarized in Table 1. These parameters are for a frequency of 100 MHz, but is assumed that similar values of the parameters will exist at 120 MHz. It should be noted that although the relative dielectric constants of phantom muscle tissue and distilled water are very similar, the electrical conductivities are vastly different. The relevant thermal characteristics---density, specific heat, and thermal conductivity---are very similar for phantom muscle tissue and distilled water.

### SIMULATION RESULTS

#### Electric Field for Array in Homogeneous Tissue

Substituting the values  $f=120$  MHz,  $\sigma=0.5$  S/m, and  $\epsilon_r=73.5$  into Equation (53) yields  $\gamma_m = 10.0 + j23.8$  for the muscle tissue. With  $\beta_m = 23.8$  radians/m, the wavelength in the phantom muscle tissue is  $\lambda_m=26.5$  cm. The attenuation constant for the muscle tissue is  $\alpha_m=10.0$  radians/m. Similarly, for distilled water  $\gamma_w = 0.0021 + j22.5$ , so the wavelength is  $\lambda_w=27.9$  cm. The attenuation constant for the distilled water medium is  $\alpha_w=0.0021$  radians/m. The propagation loss in the phantom muscle tissue is  $20\log_{10}e^{-10.0}$ , or -0.87 dB/cm. Similarly, the propagation loss in the distilled water is found to be -0.0002 dB/cm. Thus, the total loss due to propagation through 15 cm of distilled water is 0.003 dB. For 15 cm of muscle tissue the corresponding loss is 13.1 dB. The wave impedance in the muscle tissue is computed from Equation (58) as  $\eta_m = 33.9 + j14.2 \Omega$ , and similarly in the distilled water  $\eta_w = 42.1 + j0.004 \Omega$ .

FIG. 17 shows the geometry used in the simulations, which parallels the array shown in FIG. 3. A 60-cm-diameter ring phased array applicator 102 of eight perfectly conducting center-fed dipoles, 104<sub>1</sub> through 104<sub>8</sub>, uniformly surrounds a fictitious elliptical target zone 106 with major axis 30 cm and minor axis 20 cm. The length of each dipole array element

**SUBSTITUTE SHEET**

104<sub>n</sub> at 120 MHz in the infinite homogeneous muscle tissue is  $\lambda/2$ , or 13.25 cm. The array focus 107 is assumed at the origin ( $x=0$ ,  $y=0$ ,  $z=0$ ) and four auxiliary short-dipole probes, 112<sub>1</sub> through 112<sub>4</sub>, with length 1.27 cm ( $0.05\lambda$ ) are positioned at ( $x,y,z$ ) coordinates at (15 cm, 0, 0), (-15 cm, 0, 0), (0, 0, 10 cm), and (0, 0, -10 cm), respectively, i.e., the auxiliary E-field probes are located every 90° in azimuth on the perimeter of the target. In rectangular coordinates, each dipole is oriented along the  $y$  direction and the feed terminals of each dipole are located at  $y=0$ .

The moment-method computer simulations were run on a Sun 3/260 workstation. The total CPU time for a complete moment-method run is 19.2 minutes. This CPU time includes computing the quiescent and adaptive radiation patterns on a 41 by 41 grid of points. The CPU time without radiation pattern calculations is 33 seconds.

FIG. 18 shows the two-dimensional radiation pattern in the plane  $y=0$ , before nulling, at 120 MHz with uniform amplitude and phase illumination. The calculated data are collected on a 41 by 41 grid of points over a square region, with side length 76.2 cm, centered at the focus 107. The spacing between data points is 1.905 cm, or  $0.072\lambda$ , and the contour levels are displayed in 10-dB steps. The E-field data are computed for the case of a 1.27-cm short-dipole observation probe. The positions of the eight dipole radiators 104<sub>1</sub> through 104<sub>8</sub> are clearly evident by the -20 dB contours surrounding each element. The radiation pattern is symmetric because of the symmetry of the array and the assumed homogeneous medium.

FIG. 19 shows finer contour levels (1-dB steps) for the quiescent radiation pattern of FIG. 18. Here, it is evident that the focused main beam of the ring array is increasing in amplitude as the observation point moves closer to the focus. Away from the main beam region, the pattern amplitude is seen to increase as the observation position moves toward the array perimeter.

FIG. 20 shows the quiescent radiation pattern of FIG. 18 cut at  $z=0$ . The large amplitude that occurs at  $\pm 30$  cm, i.e., at the position of

SUBSTITUTE SHEET

the phased array applicator 102, is due to the E-field probe's close proximity to the transmitting elements 104<sub>1</sub> and 104<sub>5</sub>. The large attenuation that occurs from the array diameter to the focus is due to the 1/r attenuation loss and the loss in the uniform homogeneous muscle tissue. FIG. 21 shows the radiation pattern of FIG. 18 cut at  $x=0$ . Here, the pattern is identical to the pattern of FIG. 20 due to the symmetry of the array. In both FIGS. 20 and 21 the boundary of the fictitious elliptical target zone 106 is indicated. The target zone of FIG. 20 is larger than that of FIG. 21 since the major axis of elliptical target 106 lies along the x-axis, and the minor axis of target 106 lies along the z-axis.

The increasing radiation pattern amplitude near the left and right sides of the elliptical target of FIG. 20 is shown to produce hot spots in the thermal distribution. Because the top (anterior) and bottom (posterior) of the elliptical target of FIG. 21 are not as strongly illuminated as to the left and right sides of the elliptical target of FIG. 20, no quiescent hot spots occur at the top or bottom.

Further, FIG. 20 shows that the ring-array half-power beamwidth in the target region is approximately 13 cm, or approximately one-half the wavelength (26.5 cm) in the phantom muscle tissue. The adaptive nulling resolution or closest allowed spacing between a strong adaptive null and the main beam has been shown to be equal to the half-power beamwidth of the antenna. Thus, the closest allowed null position is 13 cm from the focus. Since the target width is 30 cm across the major axis, two nulls can be formed at  $(x = \pm 15 \text{ cm}, z = 0)$  at the left and right side of the target without disturbing the focus. However, if two strong nulls are formed at the posterior and anterior  $(x = 0, z = \pm 10 \text{ cm})$  of the target the focus will be compromised. In practice, the water bolus surrounding the target would restrict the placement of short-dipole probes 112<sub>n</sub> to the surface of the target. Thus, only weak nulls can be formed at  $(x = 0, z = \pm 10 \text{ cm})$  so that the focus will not be affected by the adaptive nulling process. That is, the effect of the two minor axis nulls is to keep the  $z = \pm 10 \text{ cm}$  E-field from increasing beyond the quiescent values.

SUBSTITUTE SHEET

Next, adaptive radiation patterns are computed with four auxiliary dipole probes 112<sub>1</sub> through 112<sub>4</sub> positioned as shown in FIG. 17. The value of the receiving gain for auxiliary dipole probes 112<sub>1</sub> and 112<sub>2</sub> is adjusted to produce a SNR > 35 dB. This amount of SNR results in greater than 35 dB of nulling in the direction of auxiliary dipole probes 112<sub>1</sub> and 112<sub>2</sub>. In contrast, the gain values for auxiliary dipole probes 112<sub>3</sub> and 112<sub>4</sub> are turned down to produce about a 3 dB SNR. Thus, only about 3 dB of nulling will occur at probe positions 112<sub>3</sub> and 112<sub>4</sub> as the adaptive algorithm reduces the interference to the noise level of the receiver. The reason for choosing these null strengths will become apparent with the data that follow.

FIG. 22 shows the two-dimensional radiation pattern after nulling with four auxiliary probes 112<sub>1</sub> through 112<sub>4</sub>. Two strong adaptive nulls at  $x = \pm 15$  cm occur as expected, and weak nulling occurs at  $z = \pm 10$  cm, also as expected.

The two strong nulls in the  $z=0$  cut are quantified in FIG. 23, where greater than 35 dB of interference nulling or pattern reduction occurs at  $x = \pm 15$  cm. The peak level at the focus 107 is adjusted to 0 dB for both the quiescent and adaptive patterns. Two weak adaptive nulls are seen in the  $x=0$  radiation pattern cut shown in FIG. 24. The weak nulls in effect in the adaptive patterns reduce variation from the quiescent radiation pattern.

FIG. 25(a) shows the two-dimensional radiation pattern before and after nulling taken longitudinally along a line parallel to the y-axis and passing through probe 112<sub>1</sub> as shown in FIG. 25(b), i.e.,  $x=15$  cm,  $z=0$ . This radiation pattern clearly shows that a strong adaptive null also extends in the y direction from the E-field probe being nulled.

FIG. 26(a) shows the two-dimensional radiation pattern before and after nulling taken along the y-axis and passing through the focus 107 as shown in FIG. 26(b), i.e.,  $x=0$ ,  $z=0$ . This radiation pattern clearly shows that the E-field at the focus remains virtually the same in the y direction before and after adaptive nulling at the E-field probes 112<sub>1</sub> through 112<sub>4</sub>.

SUBSTITUTE SHEET

FIG. 27(a) shows the transmit array amplitude weights before (solid line) and after (broken line) nulling, and FIG. 27(b) shows the transmit array phase weights before (solid line) and after (broken line) nulling. As shown, the adaptive transmit weights exhibit a 5-dB dynamic range in FIG. 27(a).

FIG. 28 shows the channel correlation matrix eigenvalues before (solid line) and after (broken line) nulling. There are two large eigenvalues,  $\lambda_1$  and  $\lambda_2$ , and two weak (non-zero) eigenvalues,  $\lambda_3$  and  $\lambda_4$ , shown in FIG. 28. These eigenvalues are directly associated with the two high-SNR auxiliary probes 112<sub>1</sub> and 112<sub>2</sub>, and the two weak-SNR auxiliary probes 112<sub>3</sub> and 112<sub>4</sub>, respectively. Note that the 0-dB level in FIG. 28 is equal to the receiver noise level. The probe-array output power before and after adaptive nulling is 31.4 dB and 0.9 dB, respectively, as calculated from equation (10). This difference in power before and after nulling indicates that the adaptive cancellation is -30.5 dB.

#### Temperature Distribution in Elliptical Phantom

To simulate the temperature distribution in the target body resulting from the calculated E-fields, the transient thermal analysis (TTA) software is used to compute the temperature distribution in an elliptical phantom surrounded with a constant-temperature water bolus. The 41 X 41 two-dimensional E-field radiation pattern data of FIGS. 18 through 24 are used as the power source for the thermal node network. Two node spacings are considered. First, the node spacing  $\Delta x = \Delta z = \Delta l = 1.905$  cm (coarse grid) is used to obtain thermal data. Then, the node spacing is decreased by a factor of two to  $\Delta l = 0.9525$  cm (fine grid) to check convergence. The coarser spacing is shown to be adequate.

The scale factors used to convert the normalized E-field distributions to a power level that induces a 46°C peak temperature at  $t = 20$  minutes are 94.1 dB and 96.0 dB for the quiescent and adaptive patterns, respectively. These scale factors are determined empirically. From Equations (68) through (73) and the parameter values given in Table 1, all resistors  $R_{i,j}$  in the phantom muscle tissue had a value of 96.5°C/W and

SUBSTITUTE SHEET

all resistors  $R_{ij}$  in the water bolus had a value of  $87.2^{\circ}\text{C/W}$ . The value of the capacitors  $C_i$  in the phantom muscle tissue is  $23.6 \text{ J/}^{\circ}\text{C}$ . Capacitors are not used in the water-bolus region in the input to the transient thermal analysis software. Instead, a constant temperature of  $10^{\circ}\text{C}$  is enforced at each water-bolus node. With a  $41 \times 41$  grid, a total of 3280 resistors and 1681 capacitors are used in the thermal simulation. The CPU time required to compute this temperature distribution is under four minutes.

FIG. 29 shows the two-dimensional temperature distribution produced at time  $t=20$  minutes in the elliptical phantom muscle tissue target 106 without adaptive nulling. To generate FIG. 29, the power source used in the transient thermal analysis is the quiescent radiation pattern given in FIG. 18. The initial temperature (at time  $t=0$ ) is  $25^{\circ}\text{C}$ . Notice the occurrence of two hot spots 122 and 124 on the left and right sides of the elliptical phantom, respectively. The peak temperature at focus 107 is  $46^{\circ}\text{C}$ , which is achieved by scaling the normalized quiescent E-field as described earlier. The two hot spots 122 and 124 are quantified in the  $z=0$  temperature pattern cut shown in FIG. 30, and have a peak temperature at each hot spot of approximately  $41^{\circ}\text{C}$ . The temperature profile for  $x=0$  in FIG. 31 shows no hot spots. As any undesired hot spot is a potential source for compromising the therapy session, adaptive nulling is used to reduce the sidelobes corresponding to the hot spots.

FIG. 32 shows the simulated two-dimensional thermal distribution at time  $t=20$  minutes, with adaptive nulling at four auxiliary probes  $112_1$  through  $112_4$  in effect. The focal-spot diameter at focus 107 with adaptive nulling is equivalent to the focal-spot diameter before adaptive nulling, shown in FIG. 29. Hot spots on the left and right sides of the target 106 are eliminated. FIG. 33 shows a comparison of the temperature distribution before (solid line) and after (broken line) nulling along the major axis ( $z=0$ ) of the target ellipse 106. Similarly, FIG. 34 shows the temperature distribution before (solid line) and after (broken line) nulling along the minor axis ( $x=0$ ) of the target ellipse 106.

SUBSTITUTE SHEET

The convergence of the previous thermal simulations was verified by increasing the density of E-field observation probe positions by a factor of two, with a new spacing between points of 0.9525 cm, still with a 41 X 41 grid. The ring array operates as before at 120 MHz, and there are four auxiliary probes 112<sub>1</sub> through 112<sub>4</sub> laid out as shown in FIG. 17. As the auxiliary positions are the same, the adaptive weights and channel correlation matrix eigenvalues in FIGS. 27 and 28, respectively, remain the same. From the parameter values in Table 1, all resistors  $R_{i,j}$  in the finer-grid muscle-tissue phantom had a value of 193.0°C/W and all resistors  $R_{i,j}$  in the water bolus had a value of 174.4°C/W. The value of the capacitors  $C_i$  in the phantom muscle-tissue is 2.95 J/°C. Again, a constant temperature of 10°C is enforced at each water-bolus node. The E-field scaling factors to raise the focal-point temperature to 46°C before and after nulling are 76.5 dB and 78.4 dB, respectively. The finer-grid two-dimensional thermal distributions before and after nulling are shown in FIGS. 35 and 34, respectively. Although the temperature contours are smoother, the general agreement between these patterns and the coarser-grid patterns in FIGS. 29 and 32 are evident. Similarly, one-dimensional thermal pattern cuts with the finer grid are shown in FIGS. 37 (x axis) and 38 (z axis), and good agreement with the coarse-grid patterns of FIGS. 33 and 35, respectively, is observed. In particular, the finer detail in FIG. 37 shows that the hot spots 122 and 124 are at approximately 42°C compared to 41°C observed for the coarse grid of FIG. 33. Thus, convergence of the coarse-grid thermal patterns is demonstrated.

#### Elliptical Array

An elliptical phased-array hyperthermia applicator, having a 70 cm major axis and a 60 cm minor axis, was also analyzed by computer simulation. The computer simulation parameters were the same as those applied to the analysis of the annular array. Generally, the computer simulations show that reduced hot spot temperatures are observed along the major axis of the elliptical phantom, without adaptive nulling, while

SUBSTITUTE SHEET

small increases in hot spot temperatures occur along the minor axis. Certain tumor geometries may be heated more efficiently with an elliptical array than with an annular array.

### EXPERIMENTAL RESULTS

5 Experimental data have been gathered from a commercial annular phased-array hyperthermia system modified to perform a gradient search algorithm to produce an adaptive null (or focus) at one or more auxiliary E-field probe positions. The results confirm that a strong null can be formed at the surface of the target body without significantly affecting the power  
10 delivered at the focus of the hyperthermia system.

FIG. 39 shows a cross-sectional view of the experimental system 700, which is a modified BSD-2000 SIGMA-60 annular phased-array hyperthermia applicator, available from BSD Medical Corporation, Salt Lake City, Utah. The annular array antenna 702 of the system is 59 cm in  
15 diameter and includes eight uniformly spaced dipole antennas 704<sub>1</sub> through 704<sub>8</sub>, excited with a four channel transmitter at 100 MHz. Each of the four transmit channel signals are distributed by separate coaxial cables from the hyperthermia controller (not shown) to a two-way power divider having two outputs. The two outputs of each two-way power  
20 divider drive a pair of dipole antenna elements through a pair of coaxial cables.

A cylindrical phantom target body 706 is supported by a patient sling 705 which centrally locates the phantom within the annular array so that the longitudinal axes of the phantom and the annular array correspond  
25 to each other. Phantom target 706 is a 28 cm diameter X 40 cm long polymer bottle filled with saline solution (0.9% NaCl), which simulates a human subject. A deionized water-filled bladder 705 provides a water bolus between the annular array and the target phantom.

### Single Adaptive Null

30 Three E-field probes are used to monitor the amplitude of the E-field at various sites in and around the phantom for this experiment. The first E-field probe 715 (BSD Medical Corp. Model EP-500) is located inside the

SUBSTITUTE SHEET

phantom at the center, or focus, 707 of the array which simulates the tumor site. This probe monitors the amplitude of the E-field at the tumor site as the null is formed at the null site. The second E-field probe 720 (BSD Medical Corp. Model EP-100) is taped onto the outside surface of the phantom at the desired null location which simulates an E-field probe taped to a patient's skin. The probe is used to monitor the amplitude of the E-field at the null site as the null is formed by the gradient search algorithm. The third E-field probe 721 (BSD Medical Corp. Model EP-400) is taped onto the outside surface of the phantom diametrically opposite the location of the null site probe 720. This probe is used to monitor the amplitude of the E-field away from the null and focus sites and provides an E-field amplitude reference for the experiment.

The transmit array amplitude and phase control software and the electric field probe monitoring software supplied with the BSD-2000 system were modified to incorporate a gradient search feedback routine for adaptive nulling and adaptive focusing. Pascal source code listings and sample output of the adaptive nulling and focusing gradient search feedback routines are attached hereto as Appendices C and D, respectively.

Fig. 40 graphically illustrates the results of this experiment, showing the measured E-field probe amplitude, in dB, versus the gradient search iteration number. The dB values are obtained by computing  $10\log_{10}(\text{probe output signal})$  and normalizing the resulting values to 0 dB at iteration 0. It is evident from this graph that the gradient search formed a strong E-field amplitude null at the null site, on the order of -15 to -20 dB with respect to the reference site, in less than 50 iterations. (The apparent rise in the E-field amplitude at the null site between iterations 45 and 50 is most likely due to noise associated with the convergence calculations). Furthermore, the measured E-field amplitude at the tumor site was reduced by no more than -5 dB with respect to the initial reference level. Fig. 41 shows a graphic illustration of the power, in dB, calculated at the null site versus gradient search iteration. It is evident from this graph that the

SUBSTITUTE SHEET

gradient search causes the null site power to monotonically decrease with each iteration, achieving an approximately 12 dB reduction in power within 50 iterations.

It should be noted that for at least the first 30 iterations of the  
5 gradient search, there is good agreement between the computer  
simulations, presented above, and these experimental measurements.  
After approximately 30 iterations, however, the results of the computer  
simulations differ from the experimental measurements. One reason for  
this difference is that the computer simulations herein described do not  
10 attempt to accurately model all the characteristics of the BSD-2000  
system used for the experiments. For example, the simulations do not  
account for phase shifter non-linearities, A/D convertor errors, or D/A  
convertor errors associated with the system which will affect the  
experimental measurements, especially at the relatively low signal levels  
15 present after 30 iterations. Thus, it is not expected that the computer  
simulations and the experimental results will necessarily behave the same  
where the signals or computations are most affected by measurement  
system noise.

#### Single Adaptive Null- Beef Phantom

20 Referring to Fig. 42, in another experiment, a single adaptive null  
was produced in a beef phantom 706' used in place of the saline phantom  
706 of Fig. 39 to better simulate human tissue. Beef phantom 706' was a  
24 lbs. hind leg cut having a front face width of 38 cm, a front face  
height of 23 cm and a thickness of 15 cm. The E-field probe positions  
25 used with the beef phantom are analogous to the E-field probe positions  
used with the saline phantom. That is, the first E-field probe 715' (BSD  
Medical Corp. Model EP-500) is located inside the beef phantom at the  
center, or focus, 707' of the array which simulates the tumor site. This  
probe monitors the amplitude of the E-field at the tumor site as the null is  
30 formed at the null site. The second E-field probe 720' (BSD Medical Corp.  
Model EP-100) is taped onto the outside surface of the beef phantom at  
the desired null location which simulates an E-field probe taped to a

SUBSTITUTE SHEET

patient's skin. This probe is used to monitor the amplitude of the E-field at the null site as the null is formed by the gradient search algorithm. The third E-field probe 721' (BSD Medical Corp. Model EP-400) is taped onto the outside surface of the beef phantom diametrically opposite the location of the null site probe 720'. This probe is used to monitor the amplitude of the E-field away from the null and focus sites and provides an E-field amplitude reference for the experiment.

Fig. 43 graphically illustrates the results of the beef phantom experiment, showing the measured E-field probe amplitude, in dB, versus the gradient search iteration number. Again, the dB values are obtained by computing  $10\log_{10}(\text{probe output signal})$  and normalizing the resulting values to 0 dB at iteration 0. It is evident from this graph that the gradient search formed a strong E-field amplitude null at the null site 720', on the order of -18 to -20 dB with respect to the reference site, in less than 50 iterations. Furthermore, the E-field amplitude at the tumor site was reduced by no more than -2 dB with respect to the initial reference level. It should be noted that these results are very similar to the results obtained with the saline phantom (Fig. 40).

Fig. 44 shows a comparison between the temperature rise at the beef phantom tumor site 707' and the null site 720' during nulling. A thermocouple probe was located at each of the tumor and null sites, and the RF power was applied in four intervals of 15 minutes power on and 5 minutes power off for a total experiment time of 80 minutes. The gradient search performed 10 iterations during the 15 minute power on portion of each interval. Temperature measurements were taken during the 5 minute power off portion of each interval, i.e., one measurement for each 10 iterations. The experimental data shows that the tumor site was initially at about 26°C and the null site was initially at about 27°C before applying RF power. After 40 minutes (30 minutes power on and 10 minutes power off) the temperature of the tumor site has risen 4°C to about 30°C, while the null site has risen only 1°C to about 28°C. After 80 minutes (60 minutes power on and 20 minutes power off) the temperature of the

SUBSTITUTE SHEET

tumor site has risen  $8^{\circ}\text{C}$  to about  $34^{\circ}\text{C}$ , while the temperature of the null site has risen only  $3^{\circ}\text{C}$  to about  $30^{\circ}\text{C}$ . Thus, an approximate differential of about  $4^{\circ}\text{C}$  is attained between the tissue temperature of a deep-seated target and the temperature of a single surface null site in a beef phantom.

5        Two Adaptive Nulls

In another experiment, two adaptive nulls on the surface of the saline-filled cylindrical phantom were generated and measured. This experiment used the same configuration as shown in Fig. 39 with the one E-field probe 715 (BSD Medical Corp. Model EP-500) located inside the phantom 706 at the center, or focus, 707 of the array simulating the tumor site. Two E-field probes 720 and 721 (BSD Medical Corp. Model EP-100) were located on the outside surface of the phantom at diametrically opposite positions representing the two non-invasive null sites. Probe 715 monitored the E-field amplitude at the tumor site while probes 720 and 721 monitored the E-field amplitude at the null sites.

FIG. 45 graphically illustrates the results of this experiment, showing the measured E-field probe amplitude, in dB, versus the gradient search iteration number. Again, the dB values are obtained by computing  $10\log_{10}(\text{probe output signal})$  and normalizing the resulting values to 0 dB at iteration 0. It is evident from this graph that the gradient search formed two strong adaptive E-field amplitude nulls at the null sites, on the order of -10 to -20 dB with respect to the reference site, in about 50 iterations. In particular, at iteration number 50 the null strength at probe 720 (probe site 2) is approximately -18.0 dB and the null strength at probe 721 (probe site 3) is approximately -11.8 dB. Furthermore, the E-field amplitude at the tumor site 715 (probe site 1) was held close to a constant value (0 dB) throughout the 50 iterations.

Adaptive Focusing

In another experiment, adaptive phase focusing was used to maximize the E-field amplitude at a selected location different from focus 707 of the saline-filled cylindrical phantom 706 of FIG. 39. In this case,

SUBSTITUTE SHEET

the selected focus site was at E-field probe 720 (BSD Medical Corp. Model EP-100) located on the outside surface of the cylindrical phantom.

FIG. 46 graphically illustrates the results of this experiment, showing the measured E-field probe amplitude, in dB, versus the gradient search iteration number for 30 iterations. Again, the dB values are obtained by computing  $10\log_{10}(\text{probe output signal})$  and normalizing the resulting values to 0 dB at iteration 0. The initial phase weights applied to the transmit elements of the array were equal, nominally producing an E-field focused at the center of the array 707. The gradient search was used to adjust the phases of the array transmit weights to maximize the E-field amplitude at probe site 720, i.e., refocus the array at probe 720. The transmit weight amplitudes were held constant over the 30 iterations. As shown, the gradient search converged in about 10 iterations and the power at probe 720 increased by about 0.9 dB compared to its initial value. This result demonstrates that adaptive focusing can be used successfully to optimize the peak power delivered to a tumor site.

#### Clinical Application

A modified BSD-2000 Sigma 60 system can be used as a clinical adaptive hyperthermia system for implementing the adaptive nulling and focusing techniques of this invention. An unmodified BSD-2000 hyperthermia system uses four transmit channels to energize the eight transmit elements (in pairs) of the annular array, and eight EP-400 (or EP-100) non-invasive E-field probes to monitor clinical hyperthermia treatments. The eight E-field probes can provide feedback signals to the controller performing the adaptive nulling and/or focusing algorithms. Theoretically, three independent adaptive nulls (and/or peaks) can be formed by adaptively adjusting the phases and gains of the four transmit channels. Any three of the eight E-field probes can provide the feedback signals required to produce a null (or peak) at the corresponding probe. Various treatment protocols are possible for selecting desired null sites, depending on the particular patient and case history. One protocol

SUBSTITUTE SHEET

- would place the eight E-field probes around the circumference of the patient to measure the E-field strength at each probe before nulling and thereby identify the strongest electric fields on the surface of the patient indicating potentially serious hot spots. Adaptive nulling would then be applied to minimize the electric field at the three probes having the strongest electric fields before nulling. Alternatively, if the patient can localize a painful hot spot during treatment, adaptive nulling would be applied to minimize the electric field at the E-field probe closest to the identified hot spot.
- 10 The number of adaptive nulls required will vary with patient and pathology. In some situations it is possible that more than three independent adaptive nulls will be required to achieve a therapeutic thermal distribution in the patient. In such a case, an extension of the four transmit channel BSD-2000 system to an eight transmit channel
- 15 configuration will allow up to seven independent adaptive nulls and an adaptive focus to be formed.

#### MONOPOLE ARRAY EMBODIMENT

- FIGS. 47-49 show an embodiment of a non-invasive RF monopole phased-array hyperthermia system 400 for treating malignant brain tumors. Hyperthermia system 400 features a monopole phased-array transmit antenna 402 having a plurality of monopole transmit antenna elements 404 placed in proximity to the cranium 406 of a patient to be treated for a malignant brain tumor 407. Hyperthermia system 400 also
- 20 features improved focusing characteristics through using one or more non-invasive electric field probes 412 placed on or near the patient's cranium, in conjunction with the near-field adaptive focusing and nulling apparatus and methods of this invention.

- Monopole phased-array 402 is used to therapeutically heat the brain tumor 407, typically located 1-3 cm below the skin surface of the cranium 406, by adaptively focusing the RF electric field energy radiated by the monopole radiator elements 404 into the tumor 407. In practice, it is
- 30

SUBSTITUTE SHEET

dangerous, and often impossible, to invasively place an E-field probe into the brain tumor site to facilitate adaptive focusing of the RF energy into the tumor. "Hot spots" are not typically a problem with the monopole hyperthermia array described since the side lobes generated by a phased-  
5 array in this near-field geometry are much lower than those generated by the annular phased-array described above. Thus, the monopole phased-array receives its major benefit by applying the adaptive focusing of this invention to more precisely focus energy into the tumor site. However, the adaptive nulling of this invention may also be used if "hot spots" do  
10 develop through the use of the monopole array.

The monopole phased array antenna 402 is mounted inside an water-tight enclosure 430 having a generally circular top and bottom surface 432 and 434, respectively, and a cylindrical or conical side surface 436 connecting the top and bottom surfaces. The enclosure is made from  
15 non-conductive plastic material, such as plexiglas, but may also be fashioned from any material which acts as an electrical insulator and will not interfere with the RF radiation patterns generated by the monopole phased-array inside the enclosure.

The bottom surface 434 has a central elliptical aperture 438 which  
20 accommodates a portion of the patient's cranium 406 to allow tumor 407 to be disposed within the interior of enclosure 430 adjacent to the monopole phased-array 402. A flexible silicone rubber membrane 440 covers the aperture to maintain the water-tight integrity of the enclosure. The enclosure 430 can be filled with chilled de-ionized water 442 for  
25 cooling the patient's skin during hyperthermia treatment. The de-ionized water can be temperature controlled and circulated through the enclosure 430 to maximize the cooling effect.

Bottom surface 434 also includes an RF conducting ground plane 444 mounted co-planar with the bottom surface and which acts as an RF  
30 reflector for monopole antenna elements 404. This ground plane may be fashioned out of a metal sheet, metal foil, metal mesh, or any other RF conductive material which can be fashioned to cover the area of bottom

SUBSTITUTE SHEET

surface 434. The ground plane may also be imbedded into the bottom surface by, for instance, laminating the ground plane between two layers of insulating material.

The monopole radiator elements 404 are each mounted  
5 perpendicularly onto bottom surface 434 so that they may be energized from outside the enclosure, yet remain insulated from the ground plane 444. In one preferred embodiment, each monopole radiator element 404 is a 1/4 wavelength long straight wire radiator threadably attached on one end into a connector mounted onto surface 434 and insulated from ground  
10 plane 444. It is understood that another form of a monopole antenna element, other than a straight wire radiator, can also be used. For instance, helical monopole, conical monopole, and sleeve monopole antenna elements are also appropriate for use as monopole array elements of the present invention.

15 Each monopole element is energized through a coaxial cable fed through the bottom surface 434 to the connector. The bottom surface may also be provided with extra monopole connectors which allow repositioning of the monopole radiator elements within the enclosure. Repositioning allows the user to change the geometry of the monopole  
20 phased-array antenna as well as position the antenna adjacent to the tumor location to maximize the therapeutic effect.

An RF reflecting screen 446 (FIGS. 48 and 49) can be placed behind the monopole antenna elements 404 to direct more of the radiated RF energy toward the cranium, i.e., energy which would otherwise be lost  
25 through the side of the water-tight enclosure. Reflecting screen 446 is typically positioned in the water bolus approximately 1/4 wavelength behind the monopole antenna elements and has a cylindrical reflecting surface extending perpendicularly from the ground screen to a height of approximately twice the wavelength of the radiated energy. Alternatively,  
30 the reflecting surface of the screen can be curved toward the target to further enhance radiation of the target. The reflecting screen is constructed from high frequency RF conducting mesh which allows water

SUBSTITUTE SHEET

to freely flow through it, and is electrically connected to the ground screen using good high frequency RF construction practices.

Each monopole radiator element 404 is configured as a  $1/4$  wavelength radiator to resonate at approximately 915 MHz which is effective for heating tumors 1 to 3 cm, or more, beneath the surface of the patient's skull. The monopole phased-array can include a varying number of radiator elements spatially arranged in a variety of patterns. The spacing between the monopole antenna elements is typically between  $1/2$  to 1 wavelength. Furthermore, the number and location of the non-invasive electric field probes 412 can also vary depending on the hyperthermia focusing patterns desired.

In the adaptive hyperthermia monopole phased-array of this invention, non-invasive E-field probes are used in conjunction with the adaptive focusing apparatus and techniques of this invention to maximize the RF power delivered to the tumor site inside the cranium. Computer simulations, presented herein, show that the optimum focused (e.g., with an invasive E-field probe) phased array can produce an RF energy pattern with maximum electric field strength at the tumor site and no undesired hot spots within the cranial target.

With the adaptive hyperthermia monopole phased-array described herein, RF energy peaks are adaptively formed to maximize the electric field energy delivered to the target focus. As shown, the focused energy peak achieved by the adaptive focusing apparatus of this invention is invasive to the cranial target extending into the tumor region.

Referring to FIG. 50, the adaptive-focusing monopole phased-array hyperthermia system of this invention can be described in terms corresponding to the generalized annular phased-array system schematic diagram of FIG. 6. Specifically, monopole transmit elements  $404_n$  of hyperthermia transmitting antenna array 402 correspond respectively to the dipole transmit elements  $104_n$  of annular phased array applicator 102 of FIG. 6. Furthermore, the plurality of E-field auxiliary probes  $412_m$  correspond to the E-field probes  $112_m$  of FIG. 6. It is apparent that the

SUBSTITUTE SHEET

monopole phased-array hyperthermia system herein described does not take advantage of an electric field probe placed at the tumor 407, analogous to the receiving probe 115 used with the annular phased array applicator 102 of FIG. 6, to maximize the focus radiated energy into the tumor. Use of a probe at the focus would in most cases require a surgical procedure to invasively place the probe within the patient's brain.

The receiver 114, signal processor 116, RF source 108, and weighting functions  $110_n$  (FIG. 6) operate with the monopole array as described above with regard to the annular array, except that the signal processor 116 performs an adaptive focusing algorithm described below, which is related to the adaptive nulling algorithm. That is, signal processor 116 performs either a sample matrix inversion (SMI) algorithm or a gradient search algorithm on the signals output from receiver 114 and updates the adaptive array weights  $w_n$  (with gain  $g$  and phase  $\phi$ ) to rapidly (within seconds) focus energy at the tumor 407.

Referring to FIGS. 51 and 52, there is shown an analytical model of an embodiment of an eight-element, 915 MHz hyperthermia monopole phased-array 402 of FIG. 47. Phased-array 402 has transmit antennas 404<sub>1</sub> through 404<sub>8</sub>, arranged adjacent to an elliptical phantom target 406 representing the cross section of the human cranium at the tumor level. The focus 407 of the elliptical phantom models the location, approximately 2.0 cm below the surface of the cranium, of the brain tumor to receive hyperthermia treatment, i.e., the focus of RF energy for the phased array 402. Water bolus 442 is assumed to surround the target body 406, and is treated as a homogeneous medium for analysis purposes.

The monopole radiator elements 404<sub>1</sub> through 404<sub>8</sub> are arranged as a 120° circular arc array of uniformly spaced elements having a constant radius of 12.7 cm relative to the geometric center of the cranium C, i.e., at  $x = 0.0$  cm,  $z = 0.0$  cm. The tumor site, or focus 407 of the RF energy, is assumed to be at  $x = 0.0$  cm,  $z = 5.08$  cm for simulation purposes. (In an alternative preferred embodiment the monopole array elements form a circular arc having a geometric center at focus 407

SUBSTITUTE SHEET

(target) rather than at the center of the cranium C. This has the advantage that less phase focusing should be required to maximize the energy delivered to the focus, and thus the required number of gradient search iterations is reduced.)

5 Six auxiliary RF E-field probes, or sensors,  $412_1$  through  $412_6$  (i.e., receiving antennas) are placed on and near the perimeter of the elliptical target to model non-invasive E-field probes placed on and near the skin of the cranial target. Auxiliary probes  $412_1$ ,  $412_2$ , and  $412_3$  are uniformly spaced in an arc row, between the arc array and the cranial target, having  
10 a constant radius of approximately 4.0 cm relative to the desired focus 407. Auxiliary probes  $412_4$ ,  $412_5$  and  $412_6$  are placed on the target skin adjacent to focus 407. Specifically, the first arc row of electric field probes  $412_1$  through  $412_3$  may be denoted as probes  $L_1$ ,  $M_1$ , and  $R_1$ , respectively, and the row of electric field probes  $412_4$  through  $412_6$  may  
15 be denoted as probes  $L_2$ ,  $M_2$ , and  $R_2$ , respectively. The electric field probes are arranged so that corresponding probes on the two rows are located along a radial line extending from the desired focus at tumor site 407 and are spaced  $1/4$  to  $1/2$  wavelength apart. That is, probe pair  $(L_1, L_2)$  is located along radial  $r_L$ , probe pair  $(M_1, M_2)$  is located along radial  
20  $r_M$  and, probe pair  $(R_1, R_2)$  is located along radial  $r_R$ .

The gains and phases of the monopole elements are adaptively adjusted as described below to focus the energy output from the monopole phased-array into the tumor site 407 located several centimeters below the surface of the cranium. From the phased-array geometry of Fig.  
25 52 it is observed that an electric field focused at tumor 407 will be balanced and symmetric with respect to the line  $x=0$ . Furthermore, the electric field is attenuated in the water bolus external to the cranium in the direction away from the transmit array. To achieve a focus interior to the cranium at the tumor site 407 it is assumed that the amplitude difference  
30 between the electric field adjacent to the skin surface of the cranium and the field approximately one quarter wavelength exterior to the skin surface of the cranium must be constrained to a desired value. This desired value

SUBSTITUTE SHEET

is typically a minimum to avoid "hot spots" on the skin surface. Similarly the amplitude of the electric field in the transverse direction should be balanced to minimize the electric field variation between the left and right electric field probes with respect to the middle electric field probes, i.e.,

5 maintain electric field symmetry with respect to the x-axis. The electric field differences in the radial direction may be denoted by

$$\Delta A_{L12} = |A_{L1} - A_{L2}| \quad , \quad (74)$$

$$\Delta A_{M12} = |A_{M1} - A_{M2}| \quad , \quad (75)$$

$$\Delta A_{R12} = |A_{R1} - A_{R2}| \quad . \quad (76)$$

where  $A$  denotes the amplitude of the electric field measured by the specified field probe,  $\hat{\rho}$  is a unit vector in the radial direction which bisects the transmit monopole array and  $\hat{t}$  is a transverse unit vector as shown in

10 FIG. 52. The electric field differences in the transverse direction for the first row may be denoted by

$$\Delta A_{LM1} = |A_{L1} - A_{M1}| \quad , \quad (77)$$

and,

$$\Delta A_{RM1} = |A_{R1} - A_{M1}| \quad , \quad (78)$$

and the electric field differences in the transverse direction for the second row may be denoted by

SUBSTITUTE SHEET

-65-

$$\Delta A_{LM2} = |A_{L2} - A_{M2}| \quad (79)$$

and,

$$\Delta A_{RM2} = |A_{R2} - A_{M2}| \quad (80)$$

A figure of merit  $F$  can be defined as

$$F = \alpha (\Delta A_{L12} + \Delta A_{M12} + \Delta A_{R12} + \Delta A_{LM1} + \Delta A_{RM1} + \Delta A_{LM2} + \Delta A_{RM2}) \quad (81)$$

where  $\alpha$  is a scale factor used to adjust the effect of the electrical field gradient caused by attenuation in the radial direction between the phased-array antenna and the target. The figure of merit  $F$  involves seven constraints which are easily taken into account by the eight transmit element phased-array described. The gradient search algorithm described above is used to minimize the figure of merit  $F$ .

FIG. 53 shows a simulated two-dimensional quiescent radiation pattern in the plane  $y=0$  for the eight element monopole arc array of FIG. 52 operating at 915 MHz before adaptive focusing, i.e., with uniform amplitude and phase illumination. This radiation pattern was calculated using the moment-method described above, and the calculations assume an infinite homogeneous conducting medium simulating phantom brain tissue, i.e.,  $\epsilon_r = 50.0$ ,  $\sigma = 1.3$ . The focus of the array is at  $x=0.0$ ,  $z=5.0$  cm. The positions of the eight monopole radiators 404<sub>1</sub> through 404<sub>8</sub> are clearly evident by the -10 dB contours surrounding each element. The radiation pattern is symmetric because of the symmetry of the array and the assumed homogeneous medium.

FIG. 54 shows the quiescent radiation pattern of FIG. 53 cut at  $z=5.0$  cm, which is through the tumor site 407 assumed to be at  $x=0.0$ ,

SUBSTITUTE SHEET

$z=5.0$  cm. The focused main beam is centered at  $x=0.0$  as desired. The half-power beamwidth is approximately 2.0 cm, which is close to  $1/2$  wavelength for the full ring array.

FIG. 55 shows a simulated two-dimensional thermal pattern expected for the quiescent radiation pattern of FIG. 53 at time  $t=20$  minutes. This simulation assumes that the elliptical phantom brain tissue is surrounded by a  $10^{\circ}\text{C}$  constant temperature water bolus and that the initial temperature of the brain tissue phantom is  $25^{\circ}\text{C}$ .

FIG. 56 shows a configuration of the monopole phased-array hyperthermia system of this invention configured to uniformly heat a large intra-cranial tumor target 407'. In this case, a set of auxiliary E-field probes 412 are uniformly spaced along the skin surface of the cranium between the monopole radiator elements 404 and the tumor site 407'. Here, seven E-field probes 412<sub>1</sub> through 412<sub>7</sub> are used, denoted  $P_1$  through  $P_7$  respectively, but the quantity of probes required will vary according to the tumor size and location. The gains and phases of the monopole elements are adaptively adjusted to uniformly distribute the electric field energy at the E-field probes 412<sub>1</sub> through 412<sub>7</sub>. From the geometry of FIG. 56 it is observed that a uniform electric field at the E-field probes will produce a substantially uniform electric field inside tumor 407' to induce uniform heating of the tumor.

To achieve a uniform electric field distribution across all the E-field probes, and thus uniform heating of the tumor 407', the amplitude difference between any two adjacent E-field probes on the skin surface of the cranium must be minimized. The electric field differences between adjacent E-field probes may be written as

$$\Delta A_{P12} = |A_{P1} - A_{P2}| \quad , \quad (82)$$

$$\Delta A_{P23} = |A_{P2} - A_{P3}| \quad , \quad (83)$$

$$\Delta A_{P34} = |A_{P3} - A_{P4}| \quad , \quad (84)$$

SUBSTITUTE SHEET

-67-

$$\Delta A_{P45} = |A_{P4} - A_{P5}| \quad , \quad (85)$$

$$\Delta A_{P56} = |A_{P5} - A_{P6}| \quad , \quad (86)$$

and,

$$\Delta A_{P67} = |A_{P6} - A_{P7}| \quad , \quad (87)$$

where  $A$  denotes the amplitude of the electric field measured by the specified field probe. A figure of merit  $F$  may be defined as

$$F = \Delta A_{P12}^2 + \Delta A_{P23}^2 + \Delta A_{P34}^2 + \Delta A_{P45}^2 + \Delta A_{P56}^2 + \Delta A_{P67}^2 \quad . \quad (88)$$

The figure of merit  $F$  involves six constraints on measured differences and an additional constraint on total power radiated by the transmit array, all of which are easily taken into account by the eight transmit element phased-array described. The gradient search algorithm described above is used to minimize the figure of merit  $F$  and thereby achieve a uniform electric field distribution across the E-field probes.

It should be noted that this approach for achieving a uniform electric field distribution to effect uniform heating within a large mass is not limited to the monopole array heating of a brain tumor, and for example can be similarly implemented with the annular phased-array hyperthermia applicator of FIG. 1 for uniformly heating a large mass in other areas of the body.

FIGS. 57 and 58A show an alternative preferred embodiment of the monopole phased array applicator 400 of FIG. 48 including the addition of a top ground plane surface 450 positioned above the monopole antenna elements 404<sub>n</sub> and extending from the reflecting screen 446 toward the target body parallel to ground plane surface 442. The top ground plane surface 450 combines with ground plane surface 442 to form a parallel

SUBSTITUTE SHEET

plate waveguide region 452 between the monopole antenna elements and the target body 406. The spacing between the parallel plates (i.e., between surfaces 442 and 450) can be used to adjust the radiation pattern in the direction perpendicular to the parallel plates. The spacing  
5 between the parallel plates is typically between  $1/2$  and 5 wavelengths. FIGS. 58B and 58C show alternative preferred embodiments of the parallel plate waveguide of FIG. 58A having non-parallel waveguide surfaces, and flared waveguide surface forming a horn, respectively.

FIG 59 shows a preferred embodiment of a stacked waveguide  
10 phased array applicator having multiple stacked parallel plates 450, 454, and 456 forming respective stacked waveguide regions 452, 458, and 460, each having a corresponding set of monopole phased array antenna elements  $404_n$ ,  $404_n'$ ,  $404_n''$ .

FIG. 60 shows a block diagram of a preferred embodiment of a 915  
15 MHz transmit and receive (T/R) module 800 for use with the monopole phased array hyperthermia system 400 (FIG. 47), specifically for use in transmit amplifier/phase shift network 110 of FIG. 50. Generally, the T/R module 800, as well as the monopole hyperthermia system 400, is not  
20 restricted to operate at 915 MHz, and is adaptable for operation anywhere within the industrial, scientific, medical (ISM) frequency band of 902 to 928 MHz.

The transmit function of the T/R module 800 is used to energize a monopole transmit antenna element  $404_n$  (FIG. 50) of the monopole hyperthermia array 402 with a 915 MHz signal, having controlled phase  
25 and gain, for the purposes of heating the target 407. Each monopole transmit antenna element  $404_n$  of the array 402 is connected to a corresponding T/R module and therefore the quantity of T/R modules required depends on the quantity of monopole antenna elements  $404_n$  in the array.

30 With regard to the generation of the 915 MHz transmit signal, having controlled phase and gain, a tunable oscillator 802, tunable from 180 to 206 MHz, is used to produce a transmit signal having a 193 MHz

SUBSTITUTE SHEET

center frequency. The 193 MHz transmit signal is input to a dual-stage voltage-variable attenuator 804 which covers an attenuation range of 0 to -40 dB (-60 dB off state) determined by a 12 bit analog control voltage.

The other port of mixer 808 is driven with a constant frequency 1108  
5 MHz phase-controlled signal generated by a phase-controlled local oscillator 810.

Phase-controlled local oscillator 810 is excited with a 277 MHz signal generated by a fixed frequency local oscillator 812. The output of the 277 MHz local oscillator 812 is input to a voltage-variable phase  
10 shifter which shifts the phase of the 277 MHz signal from 0 to 90°, determined by a 12 bit analog control voltage. The phase-shifted 277 MHz signal is input to a X4 frequency multiplier 816 which quadruples the signal to 1108 MHz and extends the phase control range to 0 to 360°. The output of the frequency multiplier passes through a 1108 MHz  
15 bandpass filter 818, having a 50 MHz bandwidth, to remove undesired harmonics. The 1108 MHz output of the bandpass filter is then amplified to saturation by an amplifier 820 to produce a relatively constant input power to the input port of mixer 808 independent of the commanded phase shift.

20 The upconverted, gain and phase-controlled 915 MHz signal output from mixer 808 passes through a 915 MHz bandpass filter 822, having a 50 MHz bandwidth, to remove undesired harmonics generated in mixer 808. The output signal of bandpass filter 822 passes through another T/R switch 824 which, when in the transmit position (T), connects the  
25 bandpass filter output signal to drive the input of a power amplifier 826 having an average CW output power of up to, or greater than, 100 watts. The output signal of the power amplifier 826 passes through another T/R switch 828 which, when in the transmit position (T), connects the amplified 915 MHz transmit signal to the input of another 915 MHz  
30 bandpass filter 830, having a 50 MHz bandwidth, which removes unwanted harmonics generated in the power amplifier. Finally, the 915 MHz transmit signal output from bandpass filter 830 is connected by a

SUBSTITUTE SHEET

transmission line 832 to a monopole antenna element  $404_n$  of the monopole hyperthermia array 402.

The receive function of the T/R module 800 can be used for passive microwave radiometry for non-invasively sensing the temperature of the target tissue 407 (FIG. 50) with the monopole antenna elements  $404_n$  of array 402. To operate in a non-invasive microwave radiometry mode, the transmit power is turned off as desired for a period of several seconds during which the elements of the monopole hyperthermia array act as passive receive antennas.

10 In this case, the three T/R switches 806, 824, and 828 are set to the receive (R) position. The 915 MHz center-frequency passive signal received by the monopole antenna element  $404_n$  is filtered by bandpass filter 830, amplified by a low-noise amplifier 834, and again filtered by bandpass filter 822. The output of bandpass filter 822 is mixed with the  
15 1108 MHz controlled-phase local oscillator signal by mixer 808, the output of which is input to a lowpass filter 836. Lowpass filter 836 has a 350 MHz high frequency cutoff which provides a 193 MHz center frequency receive signal for input to a second mixer 838. A variable frequency local oscillator, tunable over a 150-176 MHz range, has an output signal tuned  
20 to 163 MHz which is amplified by an amplifier 841 and input to another port of mixer 838 to mix with the 193 MHz center frequency receive signal. The output of mixer 838 contains a 30 MHz center frequency receive signal which is input to a 30 MHz bandpass filter 842, having a 5 MHz bandwidth, to remove unwanted out of band signals. The filtered 30  
25 MHz center frequency receive signal is then passed through a voltage controlled 0 to -40 dB attenuator 844 whose output signal 846 is controlled by a 12 bit analog voltage level.

The 30 MHz center frequency receive signal 846 can be analyzed with a commercial network analyzer, such as a Hewlett Packard 8510  
30 analyzer, or can be combined with the output of the other T/R modules (i.e., receive signals from the other monopole antenna elements) in a commercial analog power combiner at the 30 MHz frequency.

SUBSTITUTE SHEET

Alternatively, the 30 MHz receive signal 846 can be mixed with a 28.5 MHz local oscillator and downconverted to a baseband offset frequency of 1.5 MHz. The resulting baseband signal is lowpass filtered with a cutoff frequency of 2.0 MHz, and sampled with a high speed digital to analog  
5 convertor at 4.5 MHz (i.e., above the Nyquist sampling limit for the bandlimited signal). The frequency spectrum of the baseband signal is then computed using digital signal processing techniques (see, J.R. Johnson, et al., "An Experimental Adaptive Nulling Receiver Utilizing the Sample Matrix Inversion Algorithm with Channel Equalization", IEEE  
10 Transactions on Microwave Theory and Techniques, Vol. MTT-39, No. 5, pp. 798-808, May 1991). It should further be noted that the T/R module 800 can be used as a receiver 114 (FIG. 50) for the E-field probes 412 if the low-noise amplifier 834 is bypassed.

APPENDIX C

```

{ COPYRIGHT M.I.T. LINCOLN LABORATORY 1991, ALL RIGHTS RESERVED}
{ PROGRAM NULLGS.P (PASCAL VERSION BY ALAN J. FENN)}
{ THIS SUBROUTINE PERFORMS A GRADIENT SEARCH FOR THE}
{ ADAPTIVE NULLING WEIGHTS (AMPLITUDE AND PHASE)}
{ BASED ON MINIMIZING THE POWER RECEIVED BY AN E-FIELD PROBE}
{ AT A DESIRED NULLING POSITION. }
PROGRAM NULLGS (INPUT,OUTPUT) ;

{ PROGRAM INPUT OR FIXED PARAMETERS}

{ NCHAN IS THE NUMBER OF ADAPTIVE TRANSMIT CHANNELS (=4)}
{ NETUMOR IS THE NUMBER OF E-FIELD TUMOR-SITE PROBES (=1)}
{ NEPROBE IS THE NUMBER OF E-FIELD NULLING PROBES (=1)}
{ JSMAX IS THE MAXIMUM NUMBER OF GRADIENT ITERATIONS (=200)}
{ NBSETWT IS THE NUMBER OF BITS USED IN SETTING THE TRANSMIT WEIGHTS (=8)}
{ NBMEAWT IS THE NUMBER OF BITS USED IN MEASURING THE TRANSMIT WEIGHTS (=12)}
{ NBPROBE IS THE NUMBER OF BITS USED IN MEASURING THE E-FIELD PROBE POWER (=12)}
{ PROGRAM OUTPUT}

{ IWTAMP8 IS THE ADAPTIVE NULLING WEIGHT VECTOR AMPLITUDE}
{ IWTPH8 IS THE ADAPTIVE NULLING WEIGHT VECTOR PHASE}

{ This computer program is intended to be used in the following manner:}
{ Initially, the hyperthermia phased array should be turned on and the}
{ transmit weights are set to some nominal values. Assume that there are}
{ two E-field probes, one invasive at the desired tumor position and}
{ one noninvasive on the skin surface. The output power of the two E-field}
{ probes should be measured and be printed, saved, or displayed on the screen }
{ for reference purposes.}

APPENDIX D

```

{ COPYRIGHT M.I.T. LINCOLN LABORATORY 1991, ALL RIGHTS RESERVED}
{ PROGRAM FOCUSGS.P (PASCAL VERSION BY ALAN J. FENN)}
{ THIS SUBROUTINE PERFORMS A GRADIENT SEARCH FOR THE}
{ ADAPTIVE FOCUSING WEIGHTS (PHASE ONLY)}
{ BASED ON MAXIMIZING THE POWER RECEIVED BY AN E-FIELD PROBE}
{ AT A DESIRED FOCUS (TUMOR) POSITION. }
PROGRAM FOCUSGS (INPUT,OUTPUT) ;
{ PROGRAM INPUT OR FIXED PARAMETERS}

{ NCHAN IS THE NUMBER OF ADAPTIVE TRANSMIT CHANNELS (=4)}
{ NETUMOR IS THE NUMBER OF E-FIELD TUMOR-SITE PROBES (=1)}
{ NEPROBE IS THE NUMBER OF E-FIELD NULLING PROBES (=1)}
{ JSMAX IS THE MAXIMUM NUMBER OF GRADIENT ITERATIONS (=200)}
{ NBSETWT IS THE NUMBER OF BITS USED IN SETTING THE TRANSMIT WEIGHTS (=8)}
{ NBMEAWT IS THE NUMBER OF BITS USED IN MEASURING THE TRANSMIT WEIGHTS (=12)}
{ NBPROBE IS THE NUMBER OF BITS USED IN MEASURING THE E-FIELD PROBE POWER (=12)}

{ PROGRAM OUTPUT}

{ IWTAMP8 IS THE ADAPTIVE NULLING WEIGHT VECTOR AMPLITUDE}
{ IWTPH8 IS THE ADAPTIVE NULLING WEIGHT VECTOR PHASE}

{ This computer program is intended to be used in the following manner:}

{ Initially, the phased array should be turned on and the}
{ transmit weights are set to some nominal values. Assume that there are}
{ two E-field probes, one invasive at the desired tumor position and}
{ one noninvasive on the skin surface. The output power of the two E-field}
{ probes should be measured and be printed, saved, or displayed on the screen }
{ for reference purposes.}
{ This focusing program can do both amplitude and phase dithering if }
{ desired by uncommenting the read statement for the amplitude dither}
{ parameter and then commenting the line of code where the amplitude}

```

SUBSTITUTE SHEET

-161-

```

{ dither parameter is set equal to zero}
{ Currently, this program will only dither the transmit phase weights}

CLAIMS

1. A hyperthermia applicator for inducing a temperature rise in a target, comprising
  - 5 a plurality of electric field radiators;
  - a source of electric field radiation coupled to each electric field radiator through a controllable transmit weighting network coupled to a respective electric field radiator, each weighting network controlling the phase and amplitude of the electric field radiation transmitted by the respective electric
  - 10 field radiator in response to a respective feedback signal;
  - at least one electric field probe for detecting electric field radiation from the plurality of radiators; and
  - a controller coupled to the electric field probes for receiving the detected electric field radiation and generating
  - 15 the respective feedback signals, and for adjusting the feedback signal in response to the detected electric field radiation so that the detected electric field radiation is minimized at the electric field probe.
2. The apparatus of Claim 1, wherein the plurality of electric
- 20 field radiators comprises a phased-array of electric field transmit elements.
3. The apparatus of Claim 2, wherein the phased-array of electric field transmit elements comprises an annular array for surrounding the target.
- 25 4. The apparatus of Claims 1, 2, or 3 wherein the electric field probes comprise a plurality of probe elements disposed non-invasively along the perimeter of the target.

SUBSTITUTE SHEET

-191-

5. The apparatus of Claims 1, 2, 3, or 4 further comprising  
at least one secondary electric field probe for detecting  
electric field radiation;

5 wherein the controller adjusts the feedback signals in  
response to the electric field radiation detected by the  
secondary electric field probe so that the electric field  
radiation is maximized at the secondary electric field probe.

6. The apparatus of Claim 5, wherein the plurality of electric  
field radiators comprises a phased-array of electric field  
10 transmit elements, and the secondary electric field probe is  
disposed at the desired focus of the phased-array.

7. The apparatus of Claim 6, wherein  
the secondary electric field probe comprises at least  
one probe element disposed invasively within the target at the  
15 desired focus of the electric field energy.

8. The apparatus of Claims 1, 2, 3, 4, 5, 6 or 7 wherein the  
controller performs a matrix inversion to generate the  
feedback signal.

9. The apparatus of Claim 8, wherein the controller comprises  
20 a receiver coupled to the electric field probes for  
receiving voltages  $v_1^i, v_2^i, \dots, v_N^i$  due to the  $m$ th and  $n$ th  
electric field radiator at the  $i$ th electric field probe;  
means for forming a cross correlation  $R_{mn}^i$  of the  
received voltages, the cross correlation being given by

$$R_{mn}^i = E(v_m^i v_n^{i*})$$

SUBSTITUTE SHEET

-192-

where  $*$  means complex conjugate and  $E(\cdot)$  means mathematical expectation;

means for forming a channel correlation matrix  $R$  given by

$$R = \sum_{i=1}^{N_{aux}} R_i,$$

5 where  $N_{aux}$  is the number of electric field probes,  $R_i$  is the sample correlation matrix observed at the  $i$ th electric field probe; and

means for generating an adapted transmit weight vector  $w_a$  given by

$$w_a = R^{-1} w_q,$$

10 where generally the transmit weight vector  $w = (w_1, w_2, \dots, w_N)^T$  represents the transmit weights of each of  $N$  controllable weighting networks, and  $w_q$  represents the quiescent transmit weight vector;

15 wherein the controller adjusts the feedback signal in response to the adapted transmit weight vector  $w_a$ .

10. The apparatus of Claim 1, 2, 3, 4, 5, 6 or 7 wherein the controller performs a gradient search algorithm to generate the feedback signal.

11. The apparatus of Claim 10, wherein the controller comprises

SUBSTITUTE SHEET

-193-

a receiver coupled to the electric field probes for receiving voltage amplitudes  $|v_{1j}^i|, |v_{2j}^i|, \dots, |v_{Nj}^i|$  due to the  $m$ th and  $n$ th electric field radiator at the  $k$ th electric field probe for the  $j$ th configuration of the transmit weights  $w_{nj}$ ;

5

means for calculating a figure of merit  $F_{nj}$  from the received voltage amplitudes given by

$$F_{nj} = \sum_{k=1}^{N_{aux}} |v_{nj}^k|^2$$

where  $N_{aux}$  is the number of electric field probes,

10

means for dithering the transmit weights  $w_{nj}$  by a small amount in amplitude,  $\Delta A_{nj}$ , and phase,  $\Delta \Phi_{nj}$ ;

means for determining the figure of merit differences  $\Delta F_{Anj}$  and  $\Delta F_{\Phi nj}$  caused by dithering the amplitude and phase, respectively,

15

means for determining gradient search directions search directions  $r_{Anj}$  and  $r_{\Phi nj}$  given by

$$r_{Anj} = - \frac{\frac{\Delta F_{Anj}}{\Delta A}}{\sqrt{\sum_{n=1}^N \left[ \left( \frac{\Delta F_{Anj}}{\Delta A} \right)^2 + \left( \frac{\Delta F_{\Phi nj}}{\Delta \Phi} \right)^2 \right]}}$$

and

$$r_{\Phi nj} = - \frac{\frac{\Delta F_{\Phi nj}}{\Delta \Phi}}{\sqrt{\sum_{n=1}^N \left[ \left( \frac{\Delta F_{Anj}}{\Delta A} \right)^2 + \left( \frac{\Delta F_{\Phi nj}}{\Delta \Phi} \right)^2 \right]}}$$

SUBSTITUTE SHEET

-194-

respectively, and

means for generating the new transmit weight  $w_{n,(j+1)}$  for the  $(j+1)$ th configuration where the amplitude component of the new weight is given by

$$A_{n,j+1} = A_{nj} + \Delta A_{r_{nj}}$$

5 and the phase component of the new weight is given by

$$\Phi_{n,j+1} = \Phi_{nj} + \Delta \Phi_{r_{nj}} .$$

12. A method for inducing a temperature rise in a target, comprising the steps of:

surrounding a target with an annular phased array of electric field radiators;

10 coupling a source of electric field radiation to each electric field radiator through a controllable transmit weighting network coupled to a respective electric field radiator;

controlling the phase and amplitude of the electric field radiation transmitted by the respective electric field radiator with each weighting network in response to a respective feedback signal;

15

detecting electric field radiation from the annular phased array of radiators with a plurality of electric field probe elements disposed non-invasively along the perimeter of the target; and

20

receiving the detected electric field radiation and generating the respective feedback signals for adjusting the controllable transmit weighting network in response to the

SUBSTITUTE SHEET

-195-

detected electric field radiation so that the detected electric field radiation is minimized at the electric field probe elements.

13. A hyperthermia applicator for inducing a temperature rise in a target within a body, comprising
  - a plurality of electric field radiators;
  - a plurality of controllable transmit weighting networks, each such network coupled to a respective electric field radiator, each weighting network controlling the phase and amplitude of the electric field radiation transmitted by the respective electric field radiator in response to a respective feedback signal;
  - a source of electric field radiation coupled to each electric field radiator through a respective weighting network;
  - at least one electric field probe disposed outside the body for detecting electric field radiation from the plurality of radiators; and
  - a controller coupled to the electric field probes for receiving the detected electric field radiation outside the body and generating the respective feedback signals, and for adjusting the feedback signals in response to the detected electric field radiation outside the body so that the electric field radiation is controlled at the target inside the body.
14. The apparatus of Claim 13, wherein the plurality of electric field radiators comprises a phased-array of electric field transmit elements.
15. The apparatus of Claim 13 or 14, wherein the electric field transmit elements comprises an array of monopole antenna elements.

SUBSTITUTE SHEET

-196-

16. The apparatus of Claim 15, further comprising an RF reflecting groundplane surface for mounting the monopole antenna elements, wherein the monopole antenna elements are perpendicularly mounted to the same side of the RF reflecting ground plane, wherein the body containing the target is disposed on the same side of the ground plane as the monopole antenna elements.
17. The apparatus of Claim 16 wherein the ground plane comprises an aperture through which the body containing the target is disposed to allow positioning the target on the same side of the ground plane as the monopole antenna elements.
18. The apparatus of Claim 16 or 17 further comprising an RF reflecting screen mounted perpendicular to the groundplane surface behind the monopole antenna elements to reflect RF energy from the monopole antenna elements toward the target.
19. The apparatus of Claim 18 wherein the RF reflecting screen is positioned between  $1/8$  to  $1/2$  wavelength from the monopole antenna elements.
20. The apparatus of Claim 15, 16, 17, 18 or 19 further comprising an enclosure surrounding the monopole antenna elements and

SUBSTITUTE SHEET

-197-

providing a vessel for enclosing a bolus of fluid between the monopole antenna elements and the body.

21. The apparatus of Claim 20 wherein the vessel comprises a bolus of deionized water.
22. The apparatus of Claim 15, 16, 17, 18, 19, 20, or 21 wherein the monopole antenna elements are arranged in a circular arc of substantially constant radius.
23. The apparatus of Claim 22 wherein the body containing the target is a cranium and the radius is substantially the distance from the monopole antenna array to the center of the cranium.
24. The apparatus of Claim 22 wherein the body containing the target is a cranium and the radius is substantially the distance from the monopole antenna array to the target within the cranium.
25. The apparatus of Claim 22, 23, or 24 wherein the monopole antenna elements resonate at between 800 and 1000 MHz.
26. The apparatus of Claim 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, or 25 wherein the electric field probes comprise a plurality of probe elements disposed non-invasively along the

**SUBSTITUTE SHEET**

-198-

perimeter of the body between the elements of the phased-array and the target.

27. The apparatus of Claim 26 wherein the controller comprises means for adjusting the feedback signals to minimize the difference in the electric field detected by adjacent electric field probes and thereby provide uniform electric field radiation into the body.
28. The apparatus of Claim 27, wherein the adjusting means performs a gradient search algorithm to adjust the feedback signals.
29. The apparatus of Claim 27, wherein the adjusting means performs a matrix inversion algorithm to adjust the feedback signals.
30. The apparatus of Claim 26, wherein  
the controller comprises means for adjusting the feedback signals to provide a particular electric field pattern across the electric field probe array and thereby focus radiation into the target.

# INTERNATIONAL SEARCH REPORT

International Application No

PCT/US 92/05464

**I. CLASSIFICATION OF SUBJECT MATTER** If several classification symbols apply, indicate all<sup>6</sup>  
According to International Patent Classification<sup>7</sup> or to both National Classification and IPC  
Int.Cl. 5 A61N5/02

## II. FIELDS SEARCHED

Minimum Documentation Searched<sup>7</sup>

Classification System

Classification Symbols

Int.Cl. 5

A61N

Documentation Searched other than Minimum Documentation  
to the Extent that such Documents are Included in the Fields Searched<sup>8</sup>

## III. DOCUMENTS CONSIDERED TO BE RELEVANT<sup>9</sup>

Category <sup>10</sup>	Citation of Document, <sup>11</sup> with indication, where appropriate, of the relevant passages <sup>12</sup>	Relevant to Claim No. <sup>13</sup>
X	US,A,4 638 813 (TURNER) 27 January 1987 see column 6, line 15 - column 8, line 14	1-4 12-14, 20,21,25 5-7
A	see column 14, line 13 - column 15, line 26	
X	US,A,4 951 688 (KEREN) 28 August 1990 see the whole document	1-4, 12-14
X	US,A,4 974 587 (TURNER ET AL.) 4 December 1990 see column 4, line 21 - column 6, line 66	13,20, 21,30
X	EP,A,0 256 524 (M/A-COM, INC.) 24 February 1988 see the whole document	1,2, 13-14
	-/--	

<sup>10</sup> Special categories of cited documents : 10

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

## IV. CERTIFICATION

Date of the Actual Completion of the International Search

08 OCTOBER 1992

Date of Mailing of this International Search Report

22. 10. 92

International Searching Authority

LEMERCIER D.L.L.

## III. DOCUMENTS CONSIDERED TO BE RELEVANT

(CONTINUED FROM THE SECOND SHEET)

Category <sup>o</sup>	Citation of documents with indication, where appropriate, of the relevant passages	Relevant to Claim No.
A	IEEE TRANSACTIONS ON MICROWAVE THEORY AND TECHNIQUES vol. 39, no. 5, May 1991, USA pages 798 - 808 JOHNSON ET AL. 'An experimental adaptive nulling receiver utilizing the sample matrix inversion algorithm with channel equalization' cited in the application see the whole document	8,29
A	EP,A,0 167 670 (SIEMENS) 15 January 1986 see page 3, line 4 - page 4, line 4	13-17
A	DE,A,3 831 016 (REINBOLD) 15 March 1990 see column 3, line 56 - column 4, line 11	15
A	GB,A,624 409 (GRELL) 8 June 1949 see the whole document	18
P,A	US,A,5 101 836 (LEE) 7 April 1992 see the whole document	20-25
A	WO,A,8 001 461 (TURNER) 24 July 1980 see page 11, line 34 - page 12, line 9	1,5,12, 13

ANNEX TO THE INTERNATIONAL SEARCH REPORT  
ON INTERNATIONAL PATENT APPLICATION NO. 205464  
SA 61868

This annex lists the patent family members relating to the patent documents cited in the above-mentioned international search report.  
The members are as contained in the European Patent Office EDP file on  
The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information. 08/10/92
